Photomontage Methodology / Method Statement

Work has been completed in accordance with best practice guidelines a summary of which is provided below.

Preparation

Prior to site visit camera locations were identified and located on digital map to enable GPS routing to the correct locations. The site was “scouted” for access using Google Streetview (c) Google.

Photography

- Photographs were taken on site at locations specified using a high-resolution professional digital camera. The Camera a Canon 6D is a full frame format (which corresponds to a traditional 35mm film format) as recommended by best practice guidelines.
- Images were taken in RAW format which provides the maximum flexibility in adjustment along with the best quality available, and with bracketed exposure. The images were stored with embedded camera/photo exif data.
- The camera was tripod mounted, spirit leveled and set at a nominal 1.6m above ground level unless specifically noted otherwise on the individual images.
- The lens used was a Canon prime (fixed) 50mm or normal lens. The 50mm lens provides a similar magnification to the human eye and will provide an image which is accepted for planning uses.

Control

A series of survey points were captured on site for each photograph using Trimble R8 (or similar) survey grade VRS-GPS. The following were measured:

- The camera position, plan and height
- Measured points of detail visible when the photograph were taken. On streetscape scenes points of detail (corners of buildings, poles, signs, white lines, structures, etc) were surveyed to provide an accurate orientation base. Where insufficient existing detail is available we supplement with either with red/white ranging rods or smaller orange cones placed in the camera’s field of view while taking the photograph.
- Regardless of the type of control the configuration is designed to be non-collinear with a good photogrammetric geometry. This ensures that computational analysis was convergent.

Setting up AVR Images

- Survey and OS mapping was imported into 3D software
- A calibrated virtual 50mm camera was created to match the physical one used to capture the image. These are snapped to the surveyed locations. The individual photograph frames were loaded into the viewport.
- Using in-built software algorithms the virtual camera was adjusted so the points of detail on the photograph and the surveyed points in real-life coalesce in the camera viewport. Once complete the virtual camera was orientated so that it is identical to the physical camera that took the base photograph.
- Checks were made using the surveyed information and project mapping. This was cross referenced with the photographs to ensure they align.
- A Daylight system was then accurately introduced into the scene at it correct geo-referenced coordinates. Once the time/date and time zone is set the digital sun and skylight will match the position of the sun and shadows created by the same in the base photograph.

Verifiable Photomontage & Proposed development modelling

- The proposed development, structure, road works and earthworks was modeled up in 3D from the drawings provided by the Client / Design Team.
- The building were located in accordance with surveyed location and at the correct FFL.
- True life digital materials were designed and assigned to the 3D model elements using reference imagery provided by the client. Sophisticated real world rendering shaders were used in conjunction with the daylight system to produce final renders which will react in a verifiable manner to match the reference photographic base images.
- Finally, the new development image and the existing original photograph were merged with due care for any demolitions/removals, foreground / background existing objects, landscaping, lighting, shadows, etc. to produce a single believable and verifiable composite image.

Viewing instructions

These images are designed to be printed at A3 and taken to site to evaluate the impact of the development.

Images should be viewed with both eyes open from the locations indicated and held 500mm from the viewers eyes. (Arms length). When held at arms length the viewer should be able to effectively focus not only on the photomontage in hand but also on the surrounding landscape which will give them a much wider field of view.

When used in this fashion the existing landscape will line-up and the photomontage will provide similar perspective and thus enable the viewer to visually evaluate the proposal.

Revealed Hidden Background / Method Statement

Some of the views in this project expose areas of previously hidden background, in this case housing. A copy of these images and the relevant newly exposed background areas are highlighted here in red.

Methodology

For these images the existing trees (which are to be removed) block all views from this distance / angle. There is no option to take a matching shot from a gap or slightly elevated position. It is not possible without the removal of the intervening vegetation, which is the subject of the application to capture replacement reference photography with the same perspective and scale.

We have thus taken a series of new photographs and best matched these to provide a good representation of the level of permeability that the view will have. Since the supplementary imagery cannot exactly match the base photograph's point of view the red shaded area should be considered as representative.
