# 1 Introduction

## 1.1 BACKGROUND AND SITE LOCATION

Fluvio R&D Ltd. was commissioned by Buirios Limited, to undertake a Flood Risk Assessment (FRA) for a wind farm development at Borrisbeg, Co. Tipperary, Ireland.

This report will assess the flooding risk to the development and adjoining lands in accordance with the guidelines published by the OPW and DHELG in November 2009 "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" [1]. Additional hydraulic assessment of stream restoration works of 240(299)<sup>1</sup>m reach of River Eastwood was done and is elaborated in the Fluvio Report [2]. The assessment [2] concluded that stream restoration works do not affect flood flows / runoff downstream of works and locally improve / lower flood levels by enabling additional storage for flood flows.

The site is located east of the N62 and the townland of Borrisbeg, and north-east of Templemore in Co. Tipperary as shown in Figure 1.1.

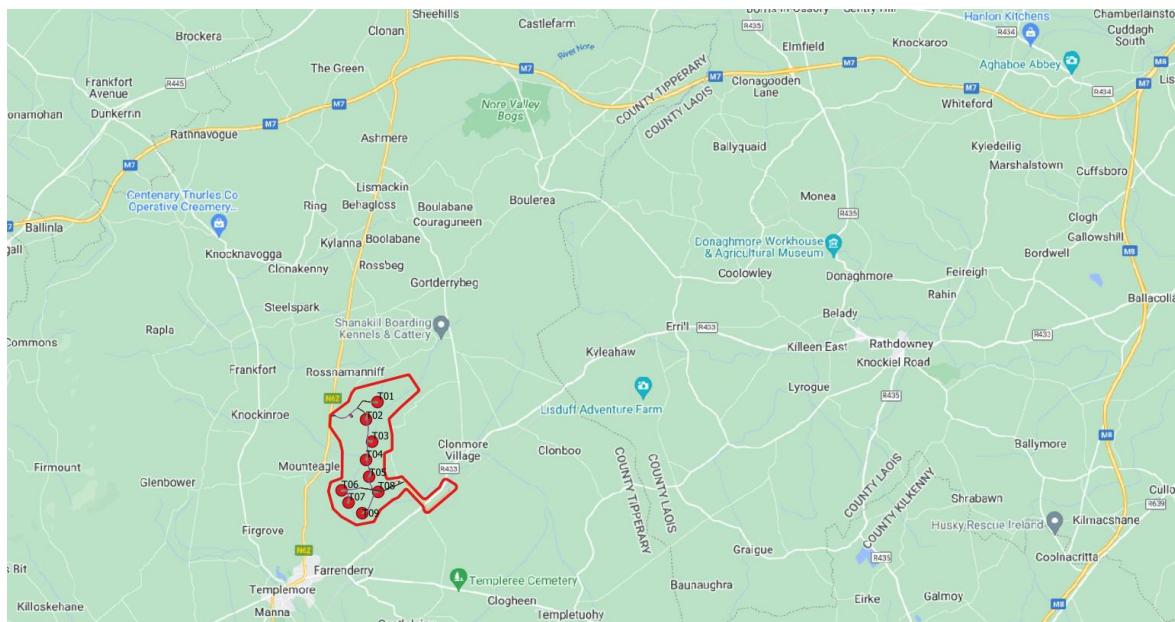

Figure 1.1. Site location.

<sup>1</sup> The length of existing channel is 240 which will be extended to 299m

### 1.1.1 Development proposal

The proposed Wind Farm (WF) (Figure 1.2) consists of nine wind turbines with hardstands and a road network. The site is bounded on the east and west sides by two main rivers – the River Suir on the east and the River Eastwood on the west. Access to the WF road network is from the N62 and a local road the L7039, both of which are not subject to flooding. Hardstands for turbines are designed with finished ground levels above the flood levels for both flood Zones A and B and the WF road network is retained at existing ground levels in order to avoid flood plain flow blockage of pre-construction flood flow paths.

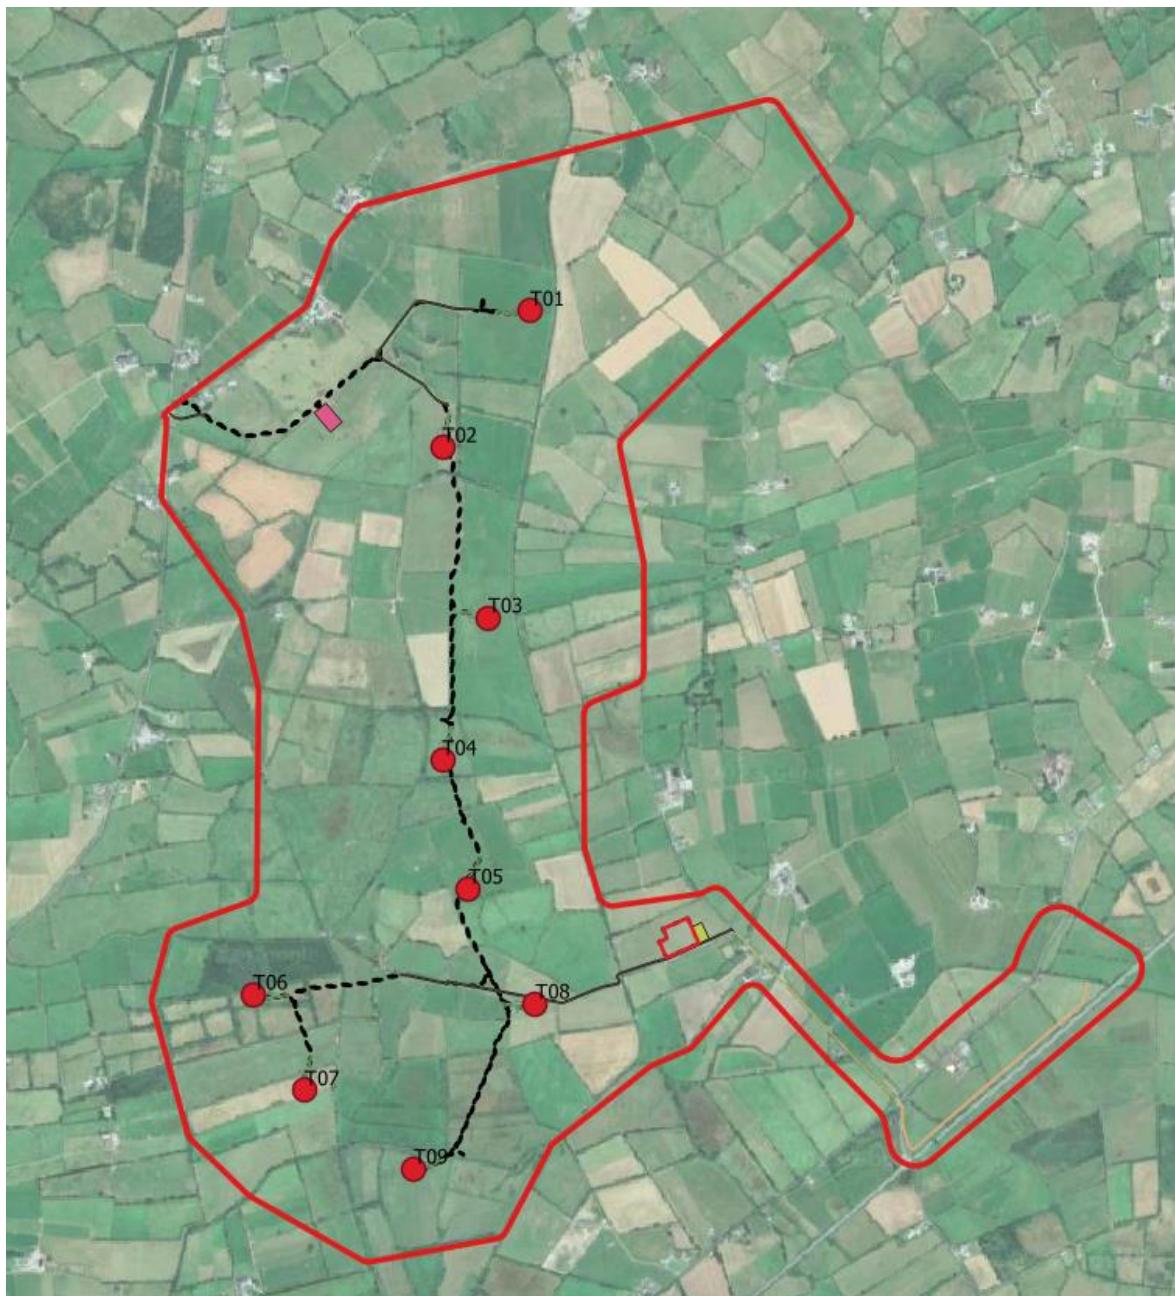

Figure 1.2. Proposed wind farm development.

## 1.1.2 Scope and objectives

The scope of this report is to provide the information necessary for a planning application by the WF developer, to discharge their responsibilities under the OPW Planning and Development Flood Policy with regard to flood risk constraints and to ensure that the development complies with the flood risk policies within Tipperary County Council's Development Plan [11]. This report has been prepared in accordance with "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" published by OPW and the Department of the Environment, Heritage and Local Government in November 2009 [1]. The aim of the FRA is to:

- Identify the flooding issues at and adjacent to the site,
- Identify and carry out the studies required to assess these.
- Design mitigation and flood alleviation measures for the development.

The risk assessment covers all sources of flooding, including the effects of run-off from the development on flood risk to the vicinity, environs and downstream of the development site. The study involves a hydrological assessment to estimate extreme river flows and examines the effect of the proposed development on these and assesses if this will have any significant impact on flooding elsewhere.

## 1.1.3 Planning and policy framework

In this Report the following Planning Framework documents were considered:

- Relevant legislation and regulations
- Irish National policy on flooding
- Local policy

### 1.1.3.1 Relevant legislation and regulations

Relevant legislation and regulations include *Arterial Drainage Acts*, *Environmental Legislation and Regulations* and *Planning and Development Management* which are presented in Annex D.

### 1.1.3.2 Irish National policy on flooding

The current Irish National policy on flood risk is outlined in the OPW document *OPW Planning and Development Flood Policy* published on [www.flooding.ie](http://www.flooding.ie). The details of the policy are presented in the Annex E.

Borrisbeg WF is not within any local area plans, as shown in Annex G. However, Tipperary County Development plan 2022-2028 Renewable Energy Strategy [12] applies to the site.

## 1.1.4 Structure of the Report

The Flood Risk Assessment (FRA) is central to the implementation of the OPW Guidelines [1]. A FRA may be undertaken over a large area, or for a particular site to:

- identify whether and the degree to which flood risk is an issue,
- identify flood zones (if not already identified),
- inform decisions in relation to spatial zoning and planning applications,
- develop appropriate flood risk mitigation and management measures for developments sited in flood risk areas.

This Report is undertaken in a sequential manner in three stages, which represent increasing levels of detail, which are: Stage 1 – Flood Risk Identification, Stage 2 – Initial Flood Risk Assessment and Stage 3 – Detailed Flood Risk Assessment. Only assessments that are needed for the purposes of decision making were carried out.

FRA's can be undertaken at a range of scales relevant to the planning process. This Report is a full FRA with a Site-Specific Flood Risk Assessment, i.e. for an individual site planning application. In accordance with the OPW Guidelines for the assessment of flood risk, the source-pathway-receptor model has been adopted. In the report, the probability of flooding occurring was calculated, the hazards that will arise were assessed, and the vulnerability of the receptors of those hazards was examined. These assessments were carried out using computer simulations of the rivers and floodplains system for existing and post-development scenarios.

## 2 Methodology

This report has been prepared in accordance with "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" published by OPW and the Department of the Environment, Heritage and Local Government in November 2009 [1].

The *Guidelines for Planning Authorities* [1] and its Technical Appendices outline the requirements for a SSFRA. The *Guidelines for Planning Authorities* requires that works:

- Avoid development in areas at risk of flooding.
- Substitute less vulnerable uses, where avoidance is not possible.
- Mitigate and manage the risk, where avoidance and substitution are not possible.

The key principles of the *Guidelines for Planning Authorities* are to apply the **Sequential Approach** to the planning process. Figure 2.1 of this report describes the mechanism of the sequential approach for use in the planning process.

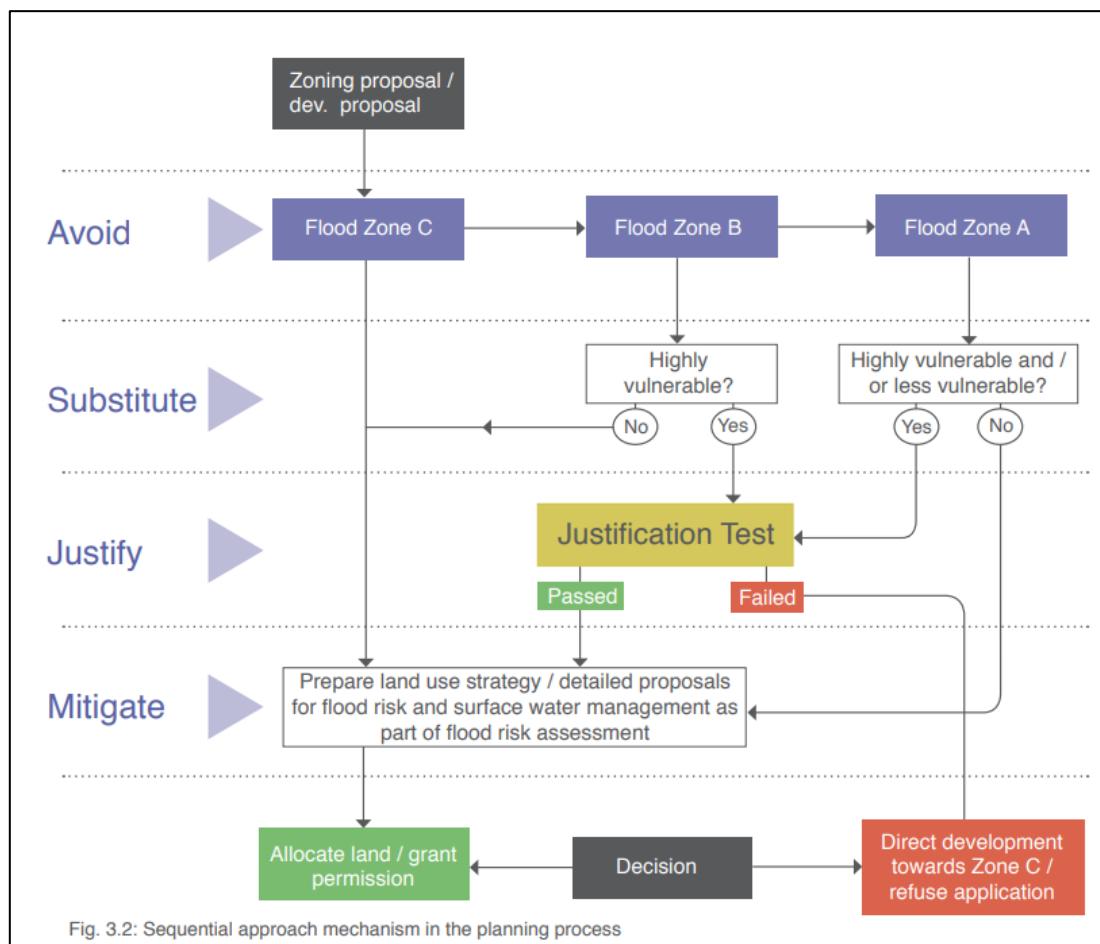

Figure 2.1: Sequential Approach Mechanism [1].

## 2.1 SOURCE-PATHWAY-RECEPTOR MODEL

The assessment of flood risk requires a thorough understanding of:

- The sources of flood water (e.g. intense or prolonged rainfall leading to runoff and increased flow in rivers).
- The pathways by which the flood water reaches those receptors (e.g. river channels, river and coastal floodplains, drains, sewers and overland flow).
- The people and assets affected by flooding (known as the receptors).

The Source-Pathway-Receptor (S-P-R) Model illustrated in Figure 2.2 has become widely used to assess and inform the management of environmental risks.

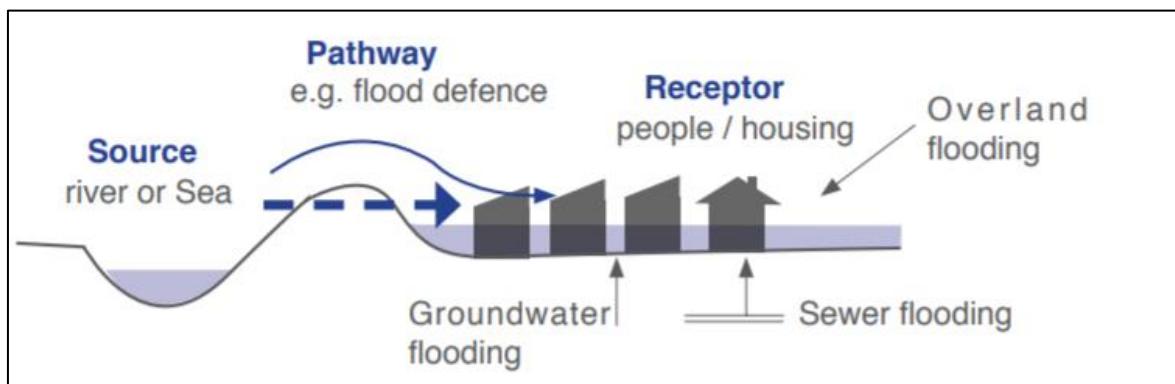

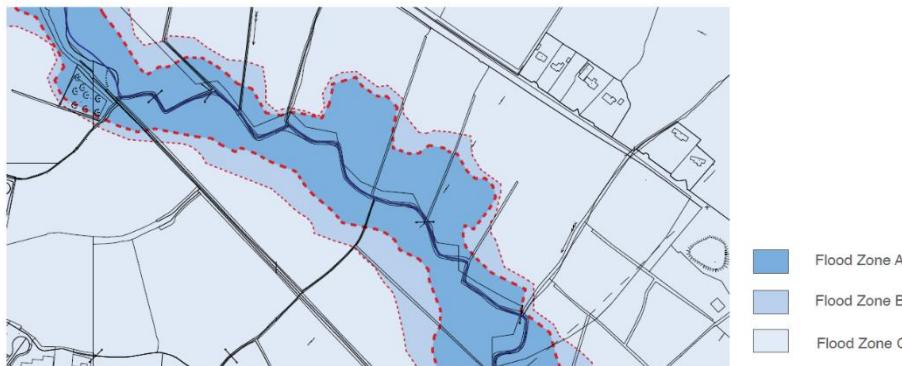

Figure 2.2: Source-Pathway- Receptor Model [1].

## 2.2 LIKELIHOOD OF FLOODING AND DEFINITION OF FLOOD ZONES

The *Guidelines for Planning Authorities* [1] define the likelihood of flooding as the percentage probability of a flood of a given magnitude occurring or being exceeded in any given year. Likelihood of flooding is expressed as a return period or annual exceedance probability (AEP).

Flood Zones are geographical areas within which the likelihood of flooding is in a particular range. They are a key tool in flood risk management within the planning process as well as in flood warning and emergency planning. These flood zones are split into three categories in the *Guidelines for Planning Authorities*.

There are three types or levels of flood zones (Figure 2.3) in accordance with the guidelines published by the OPW and DHELG in November 2009 "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" [1].

**Figure 2.3. Indicative flood zone map**

#### **2.2.1.1 Flood Zone A**

*Is the zone where the probability of flooding from rivers and the sea is highest (greater than 1% AEP or 1 in 100 for river flooding or 0.5% AEP or 1 in 200 for coastal flooding).*

#### **2.2.1.2 Flood Zone B**

*Is the zone where the probability of flooding from rivers and the sea is moderate (between 0.1% AEP or 1 in 1000 and 1% AEP or 1 in 100 for river flooding and between 0.1% AEP or 1 in 1000 year and 0.5% AEP or 1 in 200 for coastal flooding);*

#### **2.2.1.3 Flood Zone C**

*Flood zone C is where the probability of flooding from rivers and the sea is low (less than 0.1% or 1 in 1000 for both river and coastal flooding). Flood Zone C covers all areas of the plan which are not in zones A or B.*

### **2.3 CLASSIFICATION OF THE PROPOSED DEVELOPMENT AND JUSTIFICATION TEST**

The *Guidelines for Planning Authorities* categorises all types of development as either:

- Highly Vulnerable (Garda stations, ambulance stations, schools, hospitals, dwelling houses, student halls...).
- Less Vulnerable (buildings used for: retail leisure, warehousing, commercial, industrial, and non-residential institutions,...).
- Water Compatible (flood control infrastructure, docks, marinas, amenity open spaces,...).

Full list of types of development and related vulnerability classes are provided in Table 3.1 of the *Guidelines for Planning Authorities*. Uses which are not listed in the table are considered on their own merits.

The Sequential Approach restricts development types to occur within the flood zone appropriate to their respective vulnerability classes. Table 2.1 identifies the types of development appropriate for each flood zone and those that will require a Justification Test.

**Table 2.1:** Matrix of Vulnerability Versus Flood Zone [1].

	Flood Zone A	Flood Zone B	Flood Zone C
Highly vulnerable development (including essential infrastructure)	Justification Test	Justification Test	Appropriate
Less vulnerable development	Justification Test	Appropriate	Appropriate
Water-compatible development	Appropriate	Appropriate	Appropriate

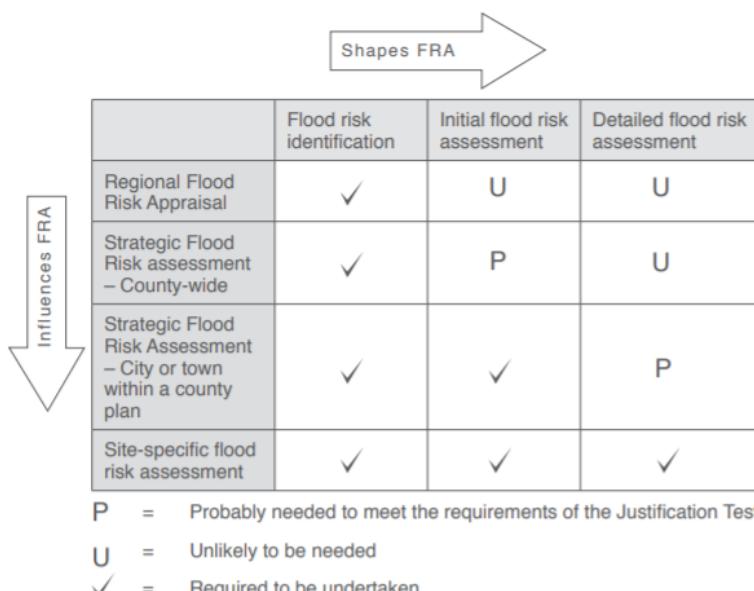

The Justification Test has been designed to rigorously assess the appropriateness of developments that are being considered in areas of moderate or high flood risk. There are two types of the Justification Test:

- The first is the Plan-making Justification Test which is used at the plan preparation and adoption stage where it is intended to zone or otherwise designate land which is at moderate or high risk of flooding.
- The second is the Development Management Justification Test which is used at the planning application stage where it is intended to develop land at moderate or high risk of flooding for uses or development vulnerable to flooding that would generally be inappropriate for that land.

## 2.4 FLOOD RISK ASSESSMENT STAGES

The *Guidelines for Planning Authorities* outline that a staged approach should be adopted when carrying out a SSFRA. These stages, see also Figure 2-3 below are:

- Stage 1 Flood Risk Identification.
- Stage 2 Initial Flood Risk Assessment.
- Stage 3 Detailed Flood Risk Assessment.

**Figure 2.4:** Flood risk assessment stages required per scale of study undertaken [1].

---

**Stage 1: Flood risk identification** – to identify whether there may be any flooding or surface water management issues relating to the proposed development site that may warrant further investigations. Flood risk identification stage uses existing information to identify whether there may be any flooding or surface water management issues related to the site. Flood risks identified in this stage are then addressed in Stage 2.

**Stage 2: Initial flood risk assessment** – to confirm sources of flooding that may affect the development site, to appraise the adequacy of existing information and to determine what surveys and modelling approach is appropriate to match the spatial resolution required and complexity of the flood risk issues. This stage involves the review of data addressed in Stage 1. Data where the flood risk at the site is recognized as being low is screened out and it is not further addressed in the report, data which recognized the flood risk on the site to be medium or high is further analysed in the report.

**Stage 3: Detailed flood risk assessment** – to assess flood risk issues in sufficient detail and to provide a quantitative appraisal of potential flood risk to a proposed or existing development, of its potential impacts on flood risk elsewhere and of the effectiveness of any proposed mitigation measures. This will typically involve use of an existing or newly developed hydraulic model which represents a wide enough area to appreciate the overall catchment-wide impacts and hydrological process involved.

## 3 Existing site conditions

The subject site is located in Borrisbeg, Co. Tipperary, Ireland. The site is located east of the N62 road and the townland of Borrisbeg and north-east of Templemore in Co. Tipperary as shown in Figure 1.1.

The site is surrounded by two main rivers – the Suir on the east and the Eastwood on the west and it is in a zone which is subject to flooding. The access to the windfarm road network is from the N62 road and the local road L7039 which are not subject to flooding.

The site itself is approximately 10.0 ha.

### 3.1 SUBSOIL AND HYDROGEOLOGY

The soil in general vicinity of the site is predominately river alluvium and Peat with some loamy drift with limestones and coarse loamy drift. The general vicinity of the site is underlain by limestone till (Carboniferous) (TLs) and Cutover peat (Cut) with some Alluvium undifferentiated (A), Rock (Rck), Limestone sands and gravels (Carboniferous) (GLs) and Lake sediments undifferentiated (L) according to the Geological Survey of Ireland (GSI). This is show on Figure 3.1.

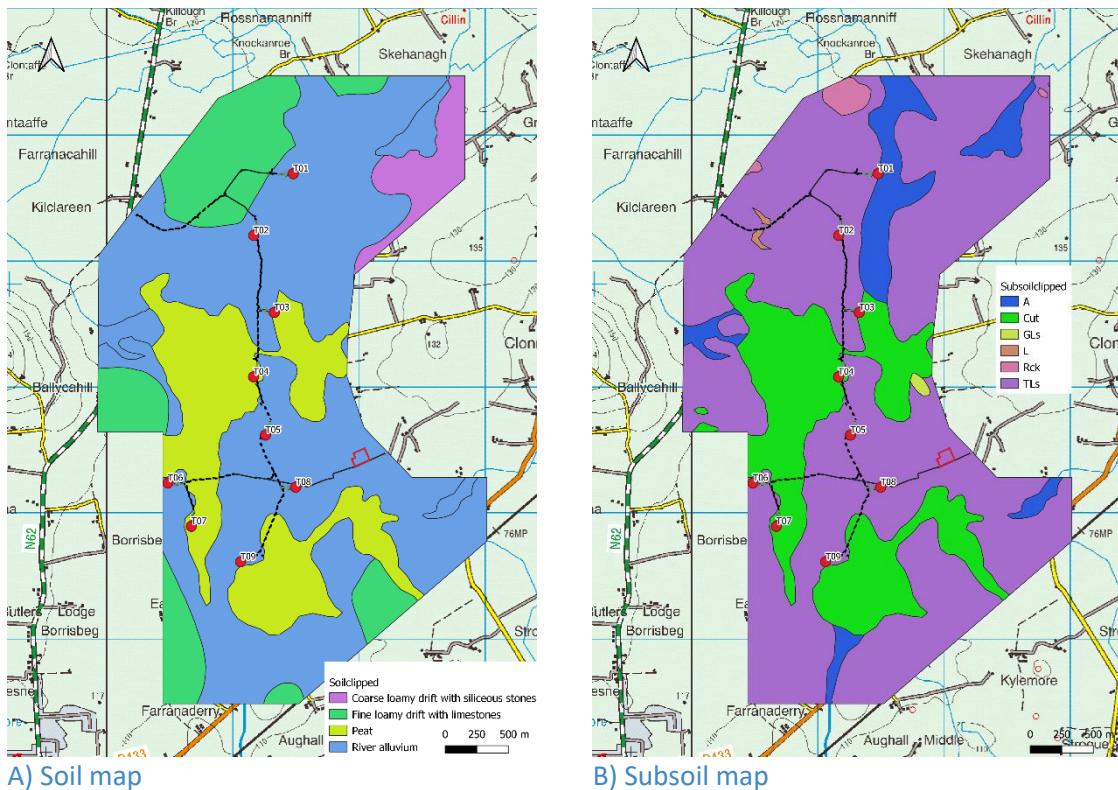

Figure 3.1

Soils Characteristics

There are no karst features located within the site. The nearest one is approximately 1 km south west in Templemore and it is classified as borehole, see Figure 3.2 below.

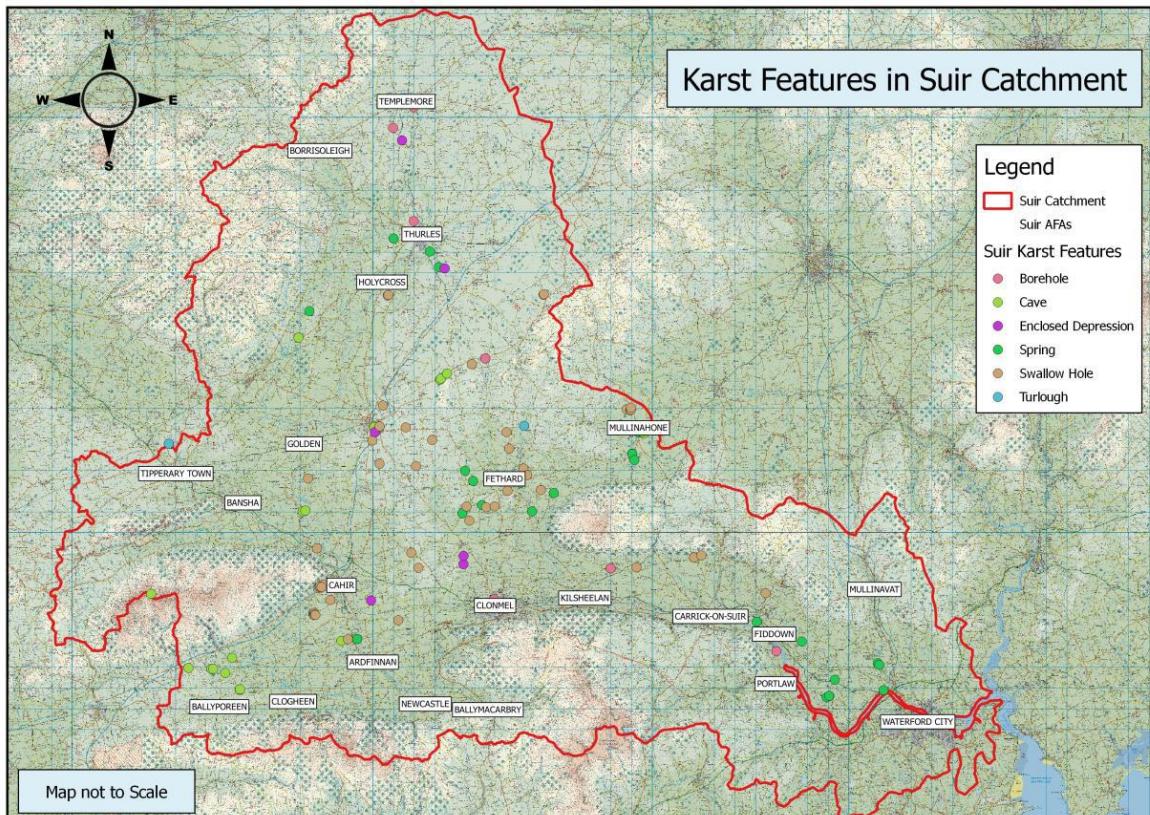

Figure 3.2. Karst features in Suir Catchment.

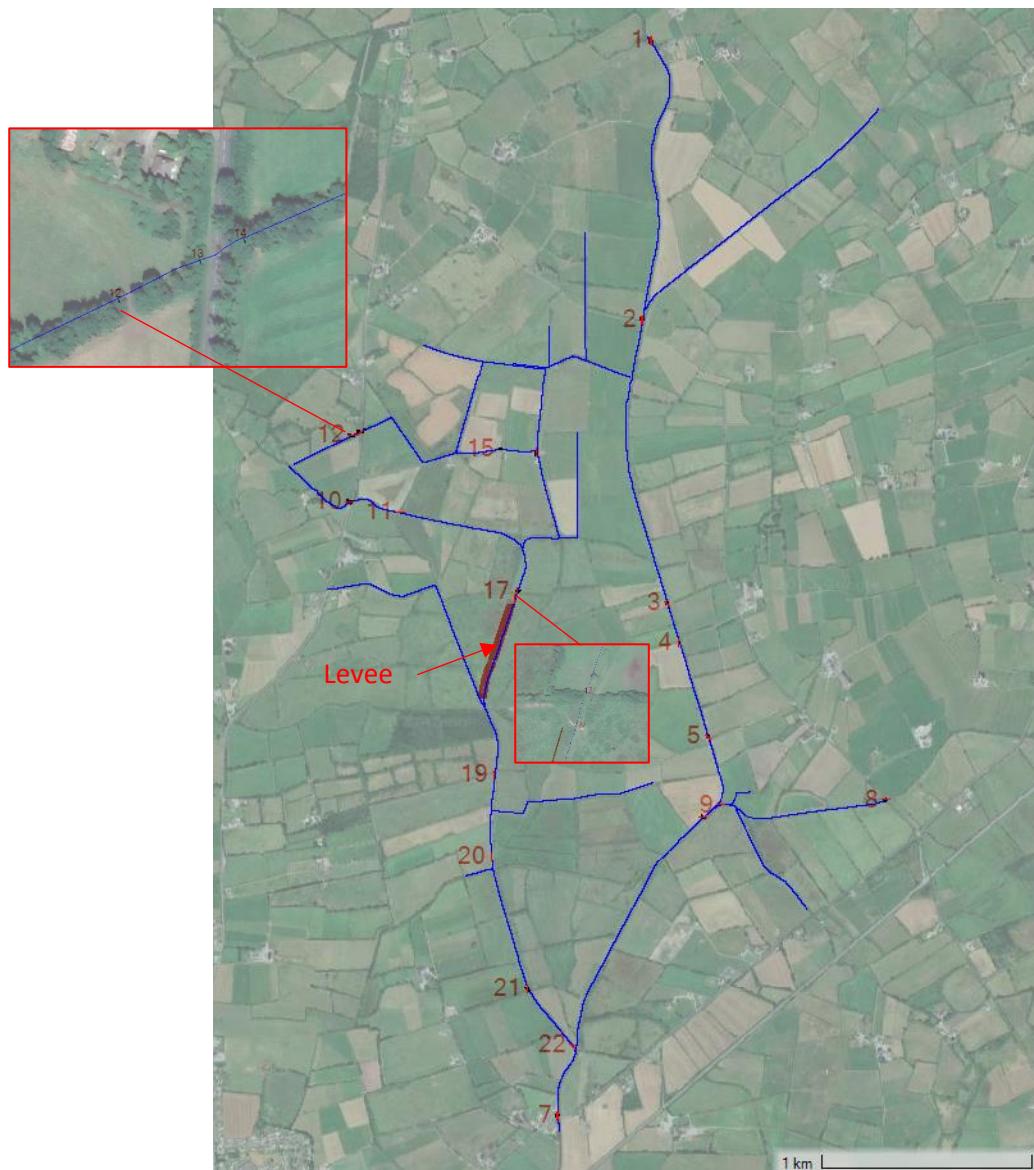

## 3.2 HYDROLOGICAL FEATURES

A site walkover survey was carried out in April 2022 to establish the pattern of existing drainage and to record existing hydrology features. The site has a gentle slope in a north – south direction. The surface runoff percolates underground while the excess water is collected by the River Suir, Eastwood Stream and field drains along the site. Photos associated with the site walkover are provided in Annex A. Identified hydrological features are shown on Figure 3.3.

In total 22 stream/river crossings have been identified within the site and adjacent to the site boundary and a single levee, these are marked on Figure 3.3 below. Property access culverts/bridges are marked from '1' to '22'. Culvert/Bridge characteristics are provided in Table 3.1. The highest ground level is at the northern part of the site, 113mOD, and the lowest point is in the south-western corner of the site, 107mOD. No local low points were identified during the site walkover. Some marsh areas with surface water ponding are located at the south side of the site where the two rivers become closer and eventually the Eastwood merges with river Suir.

**Table 3.1. Culvert details**

No	Type	Detail
1	Culvert	12-Farm Access Culvert 600mm pipe
2	Culvert	13-N62 road bridge North 770x1000mm box old stone culvert
3	Culvert	14-Farm Access Culvert 600mm pipe

**Figure 3.3. Hydrological Features**

## 4 Stage 1 - Flood Risk Identification

Flood Risk Identification is the process for deciding whether a plan or project requires a Flood Risk Assessment (FRA). It is conducted in order to identify whether there are any flooding or surface water management issues related to a proposed development site that may warrant further investigation.

### 4.1 OPW HISTORIC FLOOD MAPS

Flooding around the site area was reported on 10<sup>th</sup> June 2008 and the Winter of 2015/2016 Surface Water Flooding; see blue hatch in Figure 4.1 below. Only one wind turbine (T9) is affected by this. Benefiting lands also suggest risk of flooding along the site area.

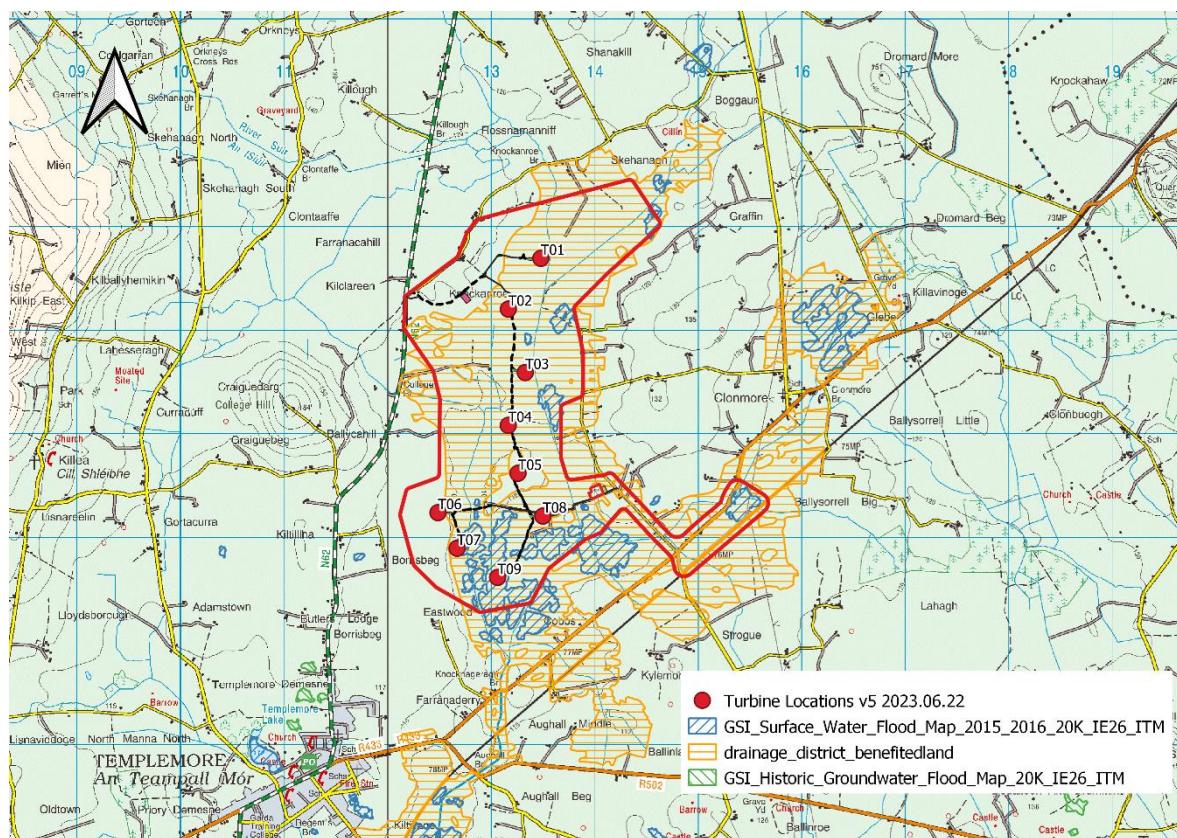

Figure 4.1. OPW flood hazard mapping [6].

The history of site flooding (10<sup>th</sup> June 2008) combined with the OPW indicative flood maps have resulted in the need for a detailed Flood Risk Assessment of the wind farm development.

## 4.2 LIKELIHOOD OF FLOODING FROM PREVIOUS STUDIES

### 4.2.1 Existing FRA

N/A

### 4.2.2 SFRA

The most recent Strategic Flood Risk Assessment (SFRA) draft plan [11] for Tipperary Co. Co does not cover the proposed site area.

### 4.2.3 Previous FRAs at national/regional, strategic and site-specific scales

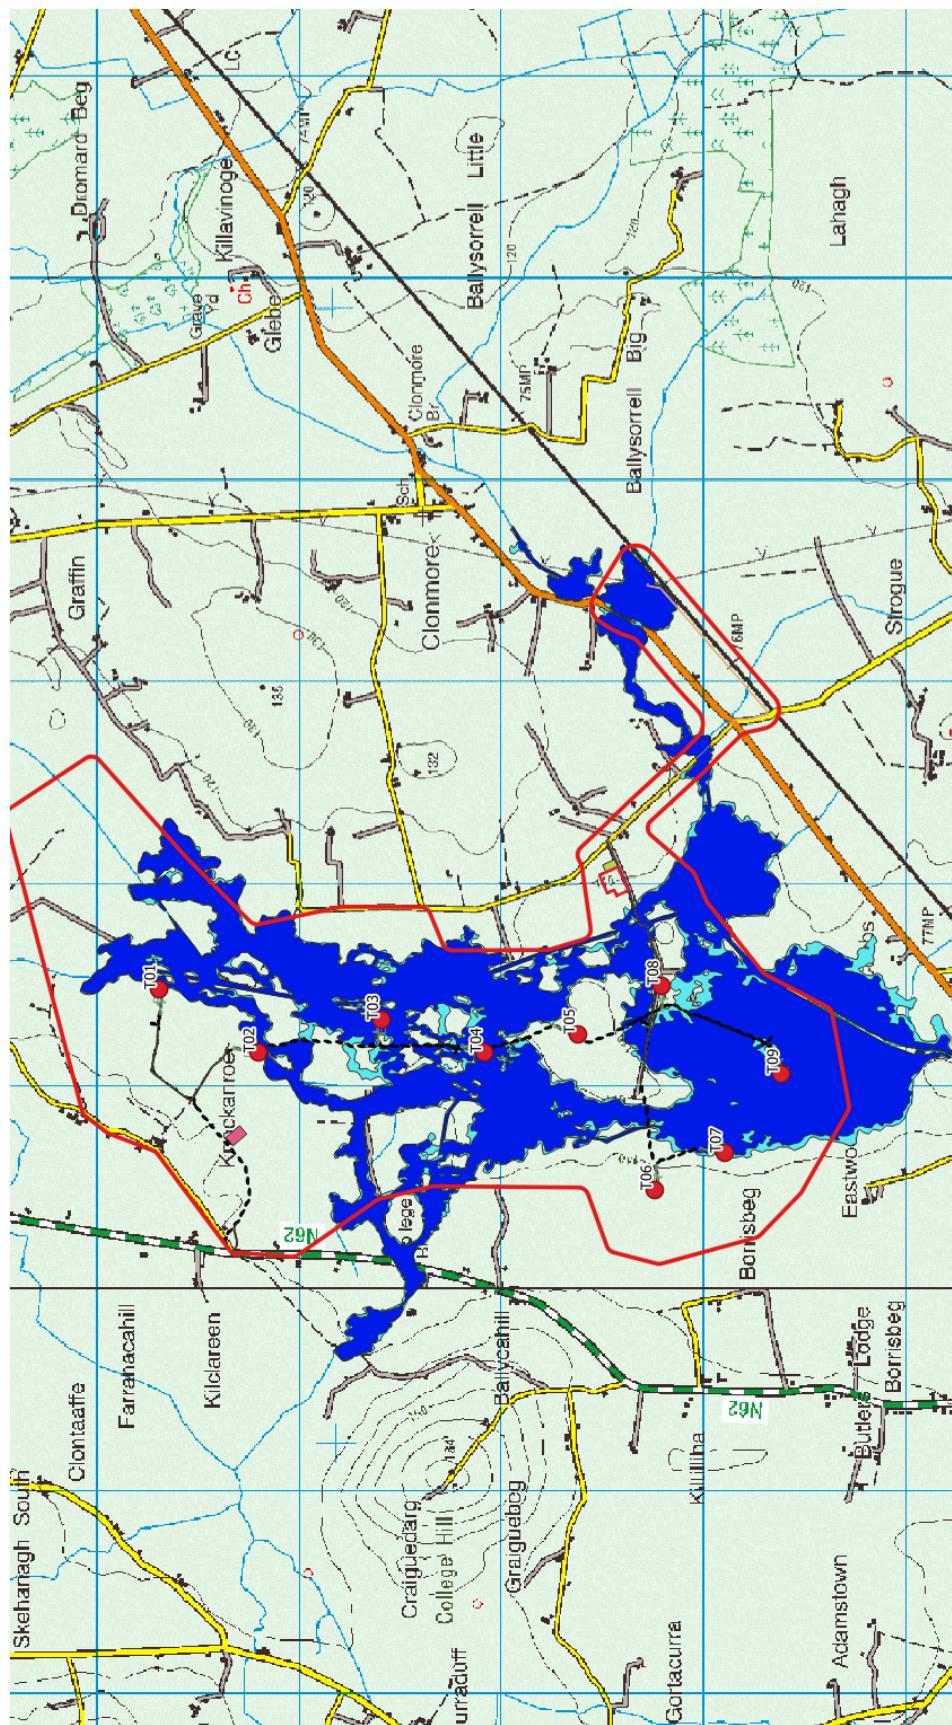

No previous FRA available.

### 4.2.4 Areas for Further Assessment and Benefiting Lands

The National Catchment Flood Risk Management (CFRAM) Programme has examined the flood risk, and possible mitigation measures to address the risk in 300 communities throughout the country at potentially significant flood risk. These communities were identified through the Preliminary Flood Risk assessment (PFRA), which was a national screening assessment of flood risk. The communities recognized as being at the significant flood risk are called Areas for Further Assessment (AFA). For the AFAs a detailed hydraulic modelling has been carried out to produce indicative flood maps (CFRAM Maps).

The subject site is not directly within an AFA (Figure 4.2) and the closest AFA is AFA160238 – Templemore [13]. Templemore AFA is not included in the Suir CFRAM as the OPW is to implement a Flood Relief Scheme [14].

The proposed site is under the OPW Maintenance of Arterial Drainage Scheme (see Annex F). The proposed wind farm is located adjacent to the River Suir and is in a zone which is subject to flooding. Indicative flood maps (Figure 4.2) produced by the OPW are available for the site and these show flooding potential at a number of locations throughout the site as shown below. The Local Authority is charged with responsibility to maintain Drainage Districts. According to the OPW database, the site drains are part of the drainage district.

Figure 4.2. Indicative Flood Maps ([floodinfo.ie](http://floodinfo.ie))

## 4.3 SOURCES OF FLOODING

### 4.3.1 Fluvial flooding

Fluvial flooding occurs when the capacity of a watercourse is exceeded or the channel is blocked or restricted and excess water spills out from the channel onto the floodplain.

According to the OPW historical flood maps (Figure 4.1) and indicative flood maps (Figure 4.2) there are clear indications that the site is located in both flood zones A and B. For OPW historical flood maps (Figure 4.1), only T09 is affected, while indicative flood maps (Figure 4.2) suggest that turbines T03, T04, T07 and T09 are affected.

It is concluded that any flooding risk from the River Suir on the east and the River Eastwood on the west has to be addressed with mitigation measures.

#### 4.3.1.1 CFRAM and NIF Maps

Although the CFRAM Fluvial Mapping does not show the site being vulnerable to fluvial flooding, this is most probably because the site area was not included in CFRAM detailed maps at the time of writing of this report. The site is only partially included in CFRAM Fluvial mapping as per Figure 4.3 below. However, the National Indicative Fluvial (NIF) mapping (Figure 4.4) shows that the site is within 1% and 0.1% AEP flood zones.

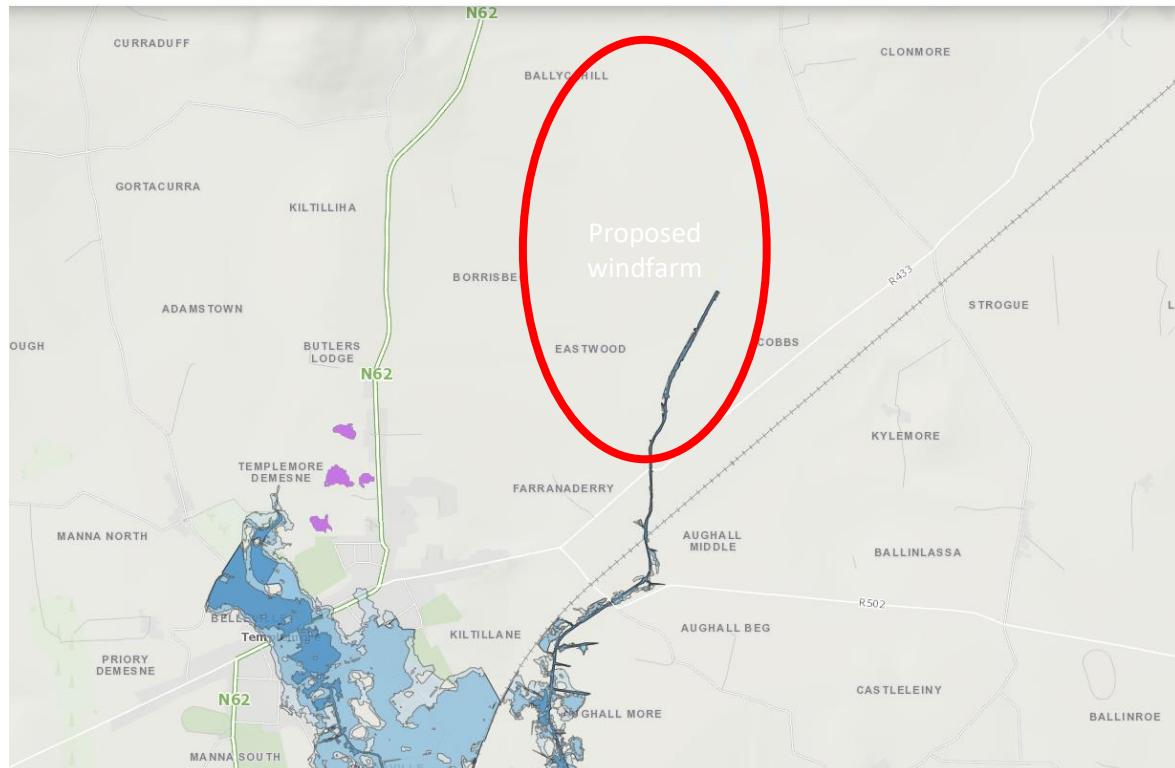

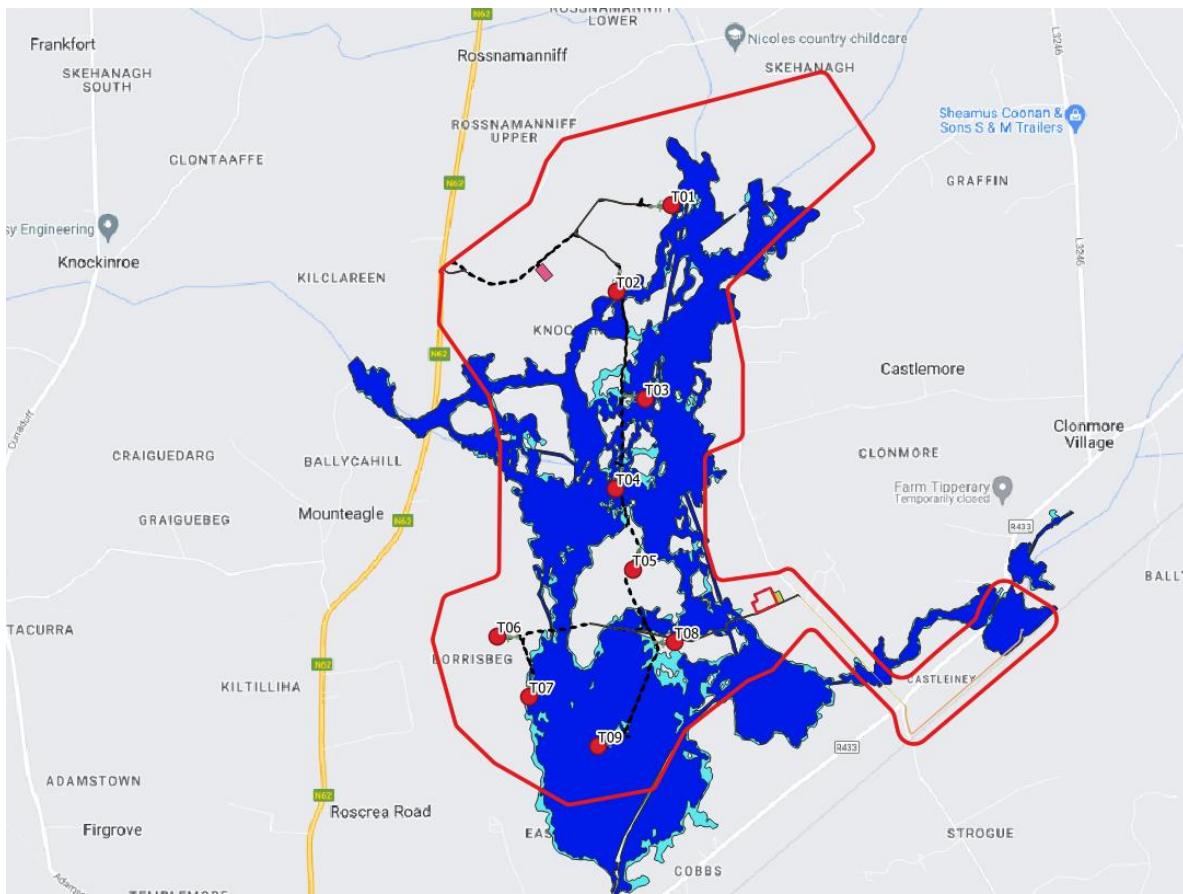

Figure 4.3. CFRAM Fluvial flood extent for 1% and 0.1% AEP (source: [www.floodinfo.ie](http://www.floodinfo.ie)).

**Figure 4.4. NIF Fluvial flood extent for 1% and 0.1% AEP (source: [www.floodinfo.ie](http://www.floodinfo.ie)).**

#### 4.3.1.2 County Development Plan

Apart from zoning within the Renewable Energy Strategy of Tipperary County Development Plan [11], the site is not within zoning of County Development Plan, see Annex F and Annex G.

#### 4.3.2 Coastal flooding

Coastal flooding which is caused by higher sea levels than normal, largely as a result of storm surges combined with high tides resulting in the sea inundating the land. Coastal flooding is influenced by the following three factors, which often work in combination: High tide levels i.e. Highest Astronomical Tide (HAT) combined with storm surges caused by low barometric pressure exacerbated by high winds and wave action which is dependent on wind speed and direction, local topography and exposure.

River(s) are not tidal around the subject site and the site is not prone to wave action due to its geographical location.

The ground levels within the site varies between 107.0mOD and 113.0mOD. **The site at no risk of coastal flooding.**

### 4.3.3 Pluvial flooding

Pluvial flood risk has been assessed using CFRAM PFRA maps (floodinfo.ie) and findings from the site visit. According to PFRA maps the subject site is not vulnerable to pluvial flooding.

The drainage of surrounding lands was noted at the time of the site visit. The site is predominately covered with grass and has a gentle slope towards the drainage channels that ensure drainage of fields into the Rivers Suir and Eastwood.

It should be noted that all proposed developments must limit the surface runoff to the greenfield rate (pre-development rate) so as not to increase the flood risk downstream of the site. The site visit in April 2022 confirmed some pluvial flooding (water ponding) at the south end of the site between the rivers Suir and Eastwood. The water table is very high and a large portion of land is marshy with no depressions.

The Winter 2015/2016 Surface Water Flooding map from GSI Groundwater Flooding Data Viewer data show fluvial (rivers) and pluvial (rain) floods in Ireland during the 2015/2016 flood event and indicate possible Pluvial / overland flooding at the site (Figure 4.5). This flooding is predominately evident at the south end of the site between the two rivers (Eastwood and Suir) where the Eastwood river meets the Suir. This ponding and very wet soil conditions were evident during the site visit. The depth of water is very low (<0.1m) and this would not cause flooding of the extended wind farm road network or turbine hard stands. This ponding influences soil conditions and makes foundation condition for turbine hardstands more challenging for design rather than posing a flood concern.

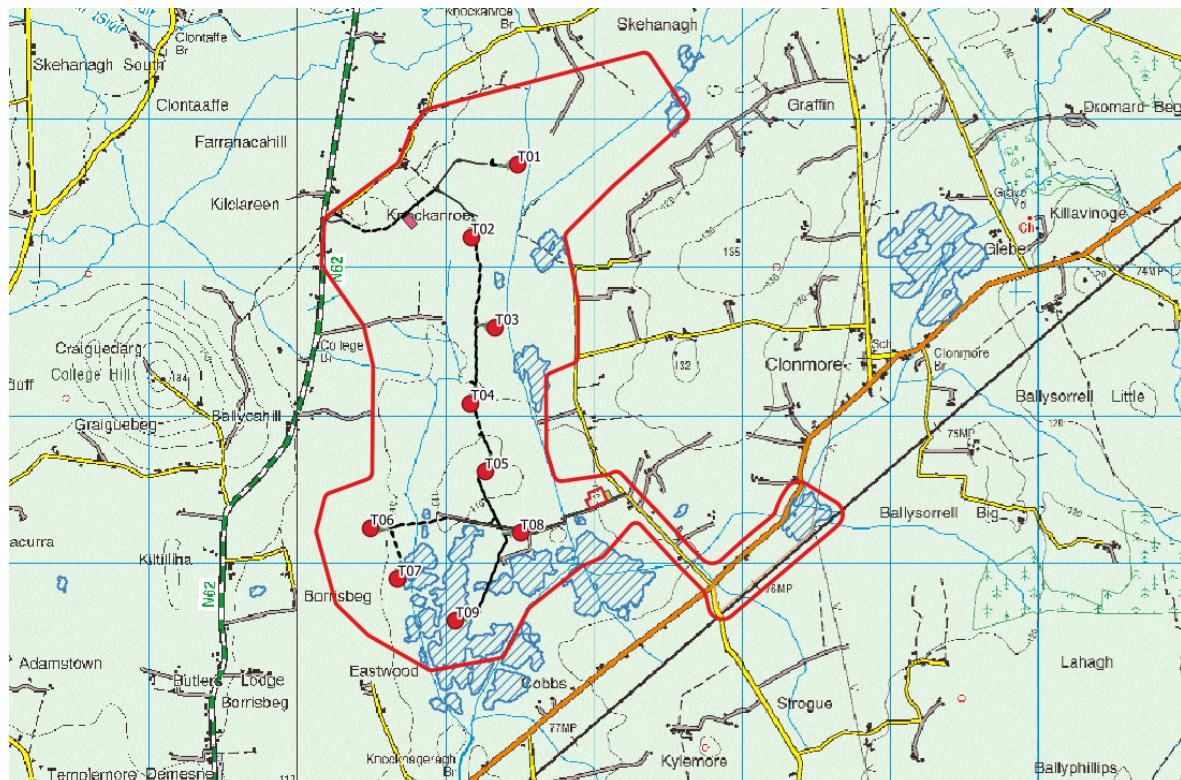

Figure 4.5. The GSI Winter 2015/2016 Surface Water Flooding map.

### 4.3.4 Overland flooding

Overland flooding occurs when the amount of rainfall exceeds the infiltration capacity of the ground to absorb it. This excess water flows overland, ponding in natural hollows and low-lying areas or behind obstructions.

Drainage channels of the surrounding fields are in operation to intercept overland flooding. Overland flooding, e.g. surface water is associated with pluvial flooding, see section above.

### 4.3.5 Groundwater flooding

Groundwater flooding occurs when the level of water stored in the ground rises as a result of prolonged rainfall to meet the ground surface and flows out over it, i.e. when the capacity of this underground reservoir is exceeded.

The terrain configuration at the site is flat and with a low slope in north to south direction (see Figure 5.6 and Figure 6.1). The subsoil at the site has lower permeability as it is underlain with Limestone till (Carboniferous) (TLs) and Cutover peat (Cut) with some more permeable Alluvium undifferentiated (A), see Figure 3.1. There are no notable ponds, depressions or karst features at the site (Figure 3.2).

GSI Groundwater flooding probability maps (Green hatch in Figure 4.1) show no risk to groundwater flooding at the site.

### 4.3.6 Flooding from artificial drainage systems

Flooding from artificial drainage systems results when flow entering a system, such as an urban storm water drainage system, exceeds its discharge capacity, the system becomes blocked, and/or cannot discharge due to a high water level in the receiving watercourse.

There several surface drainage channels within the proposed development site. The drainage channels have crossings that could be blocked or backwater could occur due to fluvial flooding of the rivers Suir and Eastwood. Therefore, the risk from drainage channel systems is linked to the fluvial flooding risk. The site falls within OPW Maintenance of Arterial Drainage Scheme. The risk of flooding from artificial drainage systems is low and is subject to maintenance under OPW jurisdiction (Figure 4.6). The Local Authority is charged with responsibility to maintain Drainage Districts. The measures prescribed by the OPW to mitigate flood risk are as follows:

- Sustainable Planning and Development Management
- Sustainable Urban Drainage Systems (SUDS)
- Adaptation Planning
- Land Use Management and Natural Flood Risk Management
- Maintenance of Channels not part of a Scheme
- Flood Forecasting and Warning
- Emergency Response Planning
- Promotion of Individual and Community Resilience
- Individual Property Protection
- Flood-Related Data Collection
- Voluntary Home Relocation

This measures are elaborated in Annex F. The local authorities have a statutory duty to maintain the Drainage Districts, and this Plan does not amend these responsibilities to provide additional flood relief.

Outside of the Arterial Drainage and Drainage District Schemes, landowners who have watercourses on their lands have a responsibility for their maintenance. Guidance to clarify the rights and responsibilities of landowners in relation to the maintenance of watercourses on or near their lands is available at [www.flooding.ie](http://www.flooding.ie).

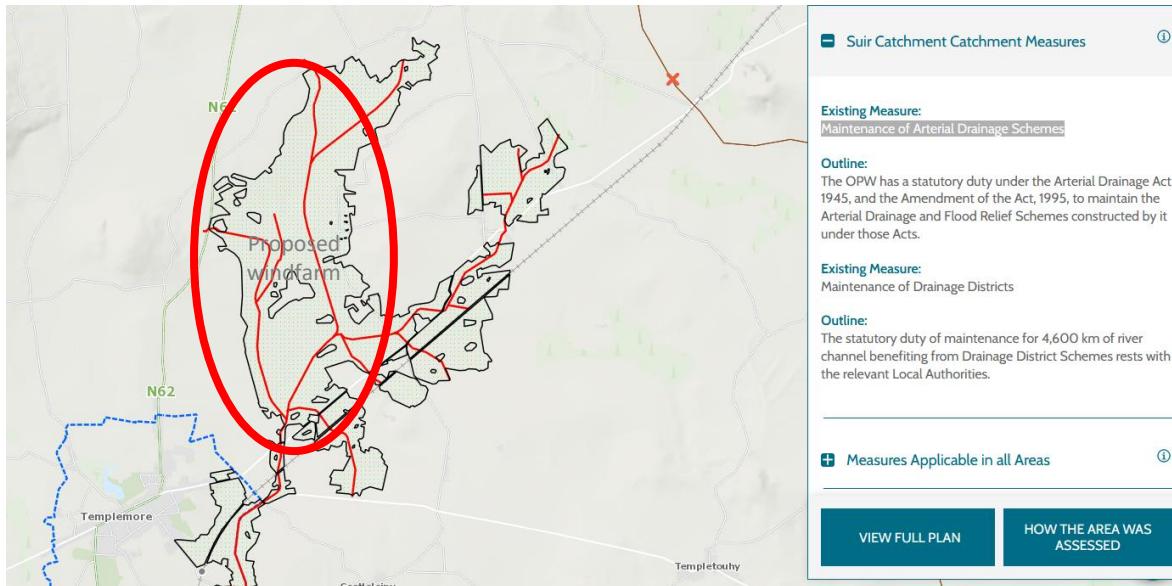

Figure 4.6. OPW Maintenance of Arterial Drainage Scheme ([www.floodinfo.ie](http://www.floodinfo.ie)).

### 4.3.7 Flooding arising from the failure of infrastructure

Flooding arising from the failure of infrastructure designed to store or carry water is a less frequent form of flooding. This type of flooding could occur due to e.g. a dam breach, a leaking canal, or a breach of flood protection measures (e.g. breach of a flood defence, failure of a non-return valve, pumping station or the blockage of a pipe or culvert).

There are no flood protection measures, e.g. dams or canals located at or near the proposed development site. A small levee is constructed along the right bank of the Eastwood stream (west side of the site – see Figure 3.3) and a very short levee at the left bank of the Suir at the south end of the site. The levee at the Eastwood stream is very low so there is low risk of failure and the levee at the Suir is wide, but short and acts more like high ground than a levee when flooding occurs. The presence of trees indicates relative stability of the river bank. Flooding arising from the failure of infrastructure is assessed to be low.

## 4.4 OTHER SOURCES

### 4.4.1 Flow gauge information

There are no gauging stations within the subject site. Station gauge No 16004 - Thurles on the River Suir has 49 years of recorded data from 1954 to 2006. The flood flows based on the Annual Maxima series were analysed in section 5.2.3.1.

## 4.4.2 Local embankments

See section 4.3.7.

# 4.5 SOURCE-PATHWAY-RECEPTOR MODEL AND DEVELOPMENT CLASSIFICATION

A Source-Pathway-Receptor (SPR) model, see Table 4.1\_summarizes the possible sources of floodwater, the receptors that maybe affected by potential flooding and the pathways by which flood water may reach the receptors. These sources, pathways and receptors will be assessed further in the Stage 2- Initial flood risk assessment

**Table 4.1: Source-Pathway-Receptor Analysis**

Source	Pathway	Receptor	Flood Risk?
Tidal/Coastal	Flood defence (Banks)	Proposed site	No
Fluvial	River Suir, River Eastwood and drainage canals	Proposed site	Yes
Pluvial	Increased runoff from developed site increasing flood levels	Proposed site	No
Groundwater (GW) flooding	Rising GW level on the site	Proposed site	No

The major flood risk at the site is from Fluvial flooding.

## 4.5.1 Mitigation measures

Proposed turbine hard stands should be constructed with finished ground level at such a height greater or equal than:

$$H_{1000} \text{ (0.1% AEP water levels)} + 0.5\text{m (freeboard)}$$

Planned road networks within the wind farm should include only widening of existing farm tracks and new access road routes should be constructed to finish surface levels of the existing adjacent floodplain in order to exclude the possibility of water backup due to blockage of existing flood flow paths within the floodplains. Crossings of the River Suir and River Eastwood should be subject to OPW Section 50 approval.

## 5 Stage 2 - Initial flood risk assessment

### 5.1 INTRODUCTION

The purpose of the initial scoping flood risk assessment is to ensure that the relevant flood risk issues are identified so that they can be addressed appropriately in the Flood Risk Assessment (FRA). The scoping phase included:

- Confirmation of sources of flooding that may affect a plan area
- An appraisal of the availability and adequacy of existing information
- Scope of possible mitigation measures

The previously conducted screening process implies that a development proposal is at risk from fluvial (river) flooding. It was concluded that the development site is at low risk of flooding from artificial drainage systems and groundwater flooding, and therefore these flood mechanisms were excluded from further investigation.

#### 5.1.1 Methodology

In order to assess the existing flooding risks associated with the development proposal, an unsteady 1D/2D computer based hydrological/hydraulic model study was carried out. The 2D model component covers an area of 10km<sup>2</sup>. The 1D model covers river reaches of c.16km, defined by 564 cross-sections and 25 bridges/culverts (the Existing River System model contains 22 bridges). The assessment also involves a hydrological analysis to determine a design flood flow.

The detailed assessment involved the following:

1. A hydrological analysis to determine the magnitude of the mean annual flood  $Q_m$ , 100-year and the 1000-year at defined HEP points.
2. Site visits to determine the extent of the river reach to be modelled based on detailed river and flood plain survey data.
3. Collection of additional survey data to develop DEM of selected river reach.
4. Computer model simulation to determine existing flood levels at the site for the design flow for the existing river and floodplain.

## 5.2 HYDROLOGY

The river flood risk is assessed on the basis of a 100-year (1% AEP) and 1000-year (0.1% AEP) flood flow hydrographs. The calculation of the design flow involved the use of the Office of Public Works Flood Studies Update (FSU) Programme<sup>2</sup> [15-18]. The FSU calculation reports are shown in Annex J. Median annual maximum flood  $Q_m$  at ungauged sites is estimated from seven catchment descriptors:

AREA, S1085, BFISOIL, SAAR, FARL, DRAIND, ARTDRAIN2.

In accordance with the OPW guidelines on hydrology, appropriate hydrological methods were used in the determination of the design peak flow which reflected the size of the catchment and the availability of river flow data in the vicinity of the wind farm site. The generation of a design flood hydrograph was necessary since we are investigating hydrological system storage effects caused by the infrastructure of the windfarm.

The following hydrological methods used for calculation of design flow rates are as follows:

- Flood Frequency Analysis from observed data
- Flood Studies Update – FSU [15].

### 5.2.1 Catchment Area

The calculation of the total catchment area at the downstream end of the model is 95.963km<sup>2</sup>, see Figure 5.1. The effective contributing catchment area is calculated as:

$$\text{Catchment area, } A = 95.963\text{km}^2.$$

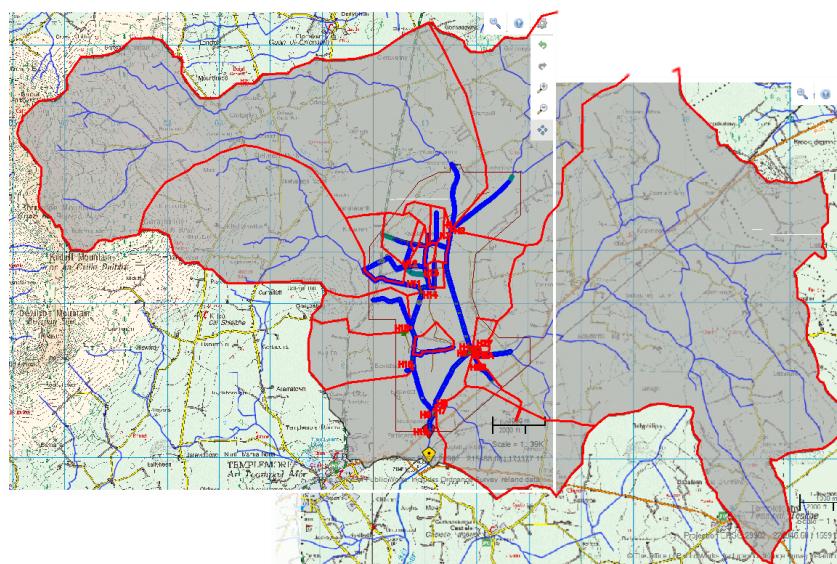

Figure 5.1. Catchment area delineation for all HEPs.

<sup>2</sup> Office of Public Works, Flood Studies Update, Technical Research Report, Volumes I-IV, 2014.

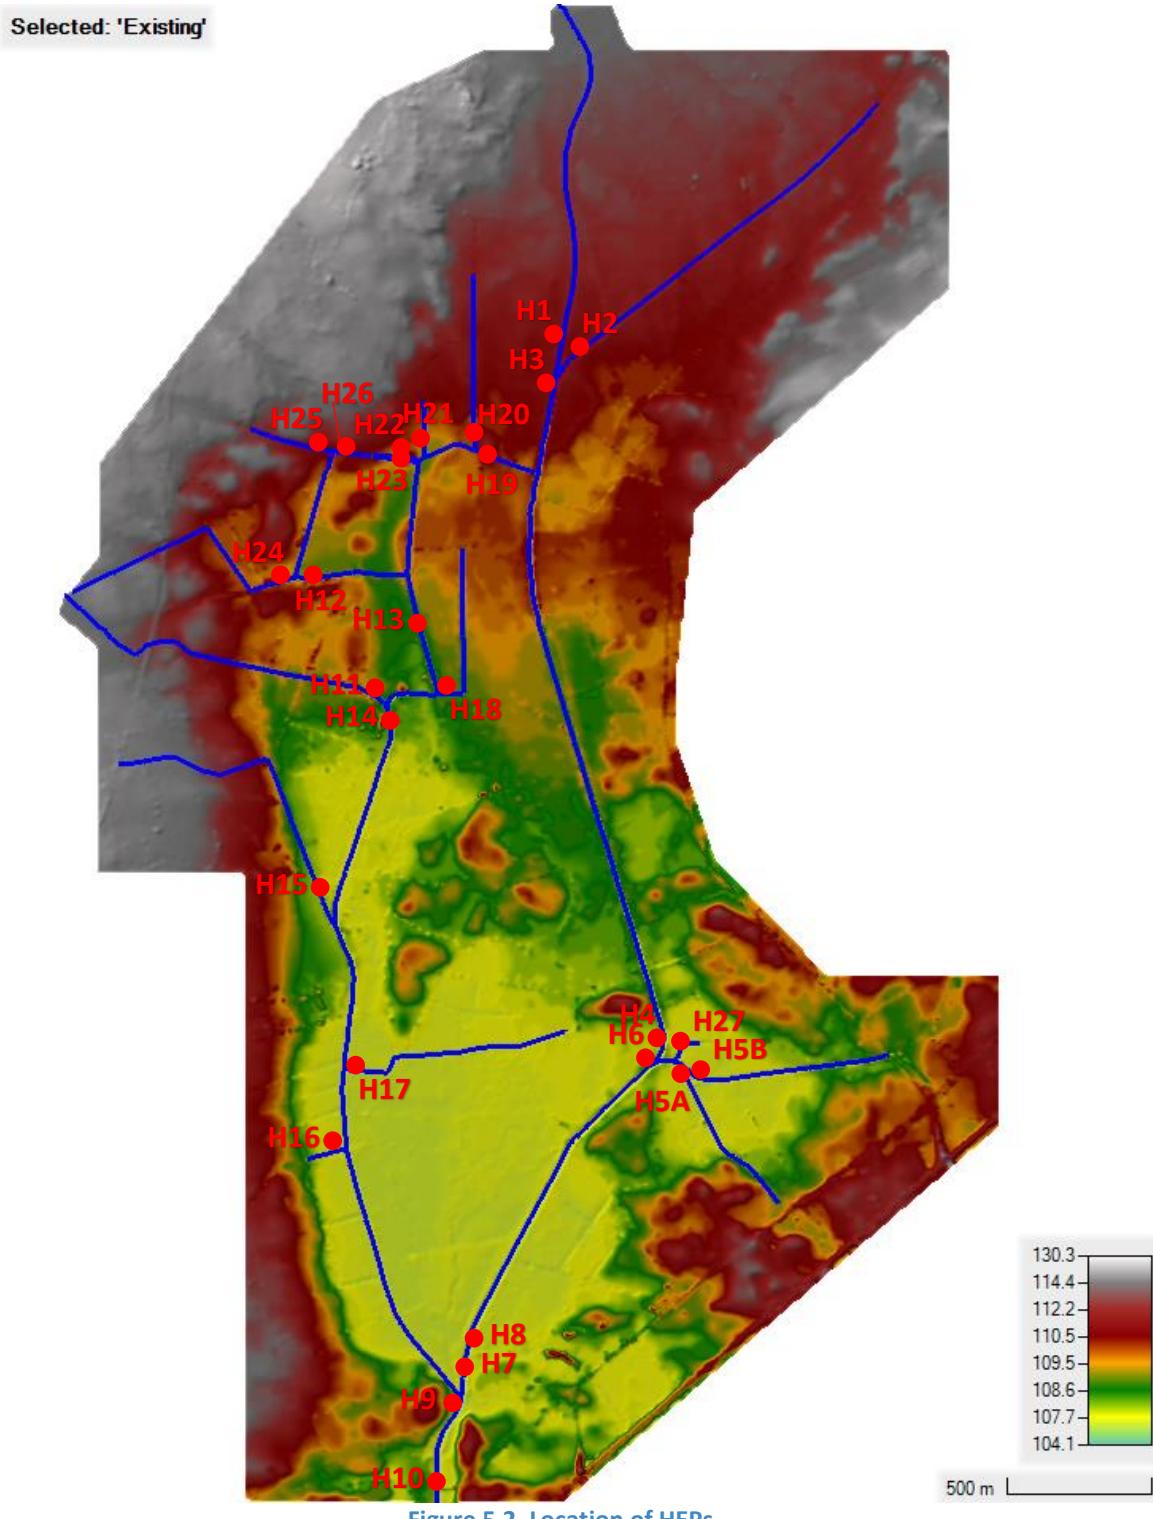

## 5.2.2 Hydrological Estimation Points - HEPs

As stated in the Section above, the FRA requires a high resolution hydrological analysis due to the fact that the OPW Indicative flood maps show flooding. The hydrological model for the wind farm site therefore is complex involving the combination of a number of tributaries and drainage channels.

Each of the tributaries is hydrologically assessed separately and the runoff is calculated for a set of Hydrological Estimation Points (HEPs). The locations of the HEPs are shown in Figure 5.2 below. The breakdown of the contributing catchment areas for each HEP is given in the Table 5.1 below.

**Table 5.1. Contributing catchment area for each HEP**

Catchment area [km <sup>2</sup> ]							
H1	H2	H3	H4	H5A	H5B	H6	H7
22.243	11.911	34.877	37.089	35.253	0.332	72.495	77.438

<b>H24</b>	<b>H25</b>	<b>H26</b>	<b>H27</b>				
0.591	0.383	0.026	0.212				

## 5.2.3 Design Flow Rates

### 5.2.3.1 Flood Frequency Analysis from observed data

#### 5.2.3.1.1 Input data for gauge No 16004 - Thurles

The relevant gauging station for the River Suir is located just upstream of Thurles. The gauge is owned, monitored and maintained by OPW. The gauge has provided water level and flow rate records since 1954 (49 years of Amax series flow records was available for the analysis). The gauging point has a catchment area of 228.74km<sup>2</sup>. The catchment characteristics are shown in Table 5.2. The Amax Series from 1954 to 2002 is shown below.

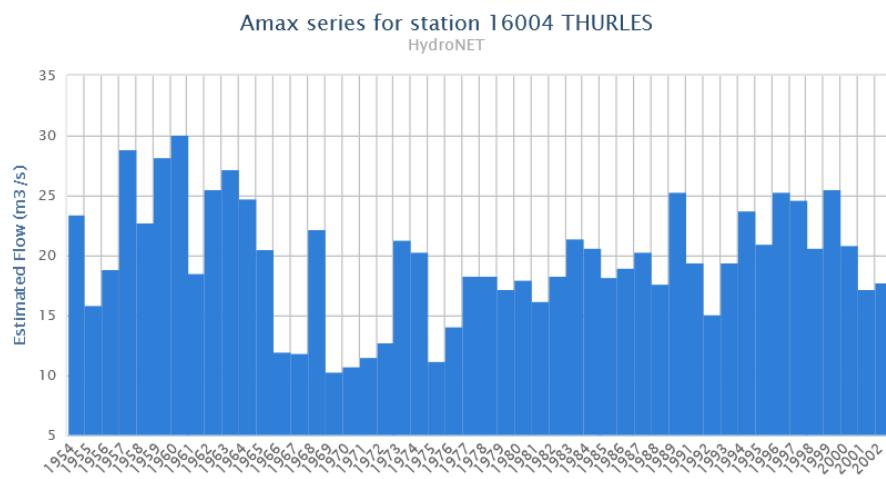

Figure 5.3. Amax series for OPW gauge No 16004 – Thurles on Suir.

Table 5.2. Catchment characteristics for gauge 16004 on Suir, Thurles.

Contributing Catchment Area	228.7432 km <sup>2</sup>
BFISOIL	0.5786
SAAR	941.36 mm
FARL	1
DRAIND	0.915 km/km <sup>2</sup>
S1085	1.7914 m/km
ARTDRAIN2	0
URBEXT	0.0109
Centroid distance	7.6626 km
Hydrological similarity	0.7169

Pivotal PCD urban	27.9609m <sup>3</sup> /s
Subject PCD estimate	16.6089m <sup>3</sup> /s
68% upper bound	22.7542m <sup>3</sup> /s
68% lower bound	12.1233m <sup>3</sup> /s
95% upper bound	31.1733m <sup>3</sup> /s
95% lower bound	8.8491m <sup>3</sup> /s

### 5.2.3.1.2 CFRAMS design flows for gauge No 16004 - Thurles

OPW CFRAMS study data are available. (The OPW conducted a Flood Frequency Analysis for Thurles station and their results gave a similar value of  $Q_{100} = 35.64\text{m}^3/\text{s}$ ). The design flows from CFRAMS are shown in Table 3 below.

**Table 5.3. Flood Frequency analysis for Station 16004 – Thurles.**

AEP	16004
50%	20.72
20%	25.28
10%	27.97
5%	30.46
2%	33.36
1%	35.64
0.50%	37.71
0.10%	42.48

In addition to CFRAMS analysis [15], an independent statistical analysis of Amax series was conducted as part of this report. This is elaborated in the following section.

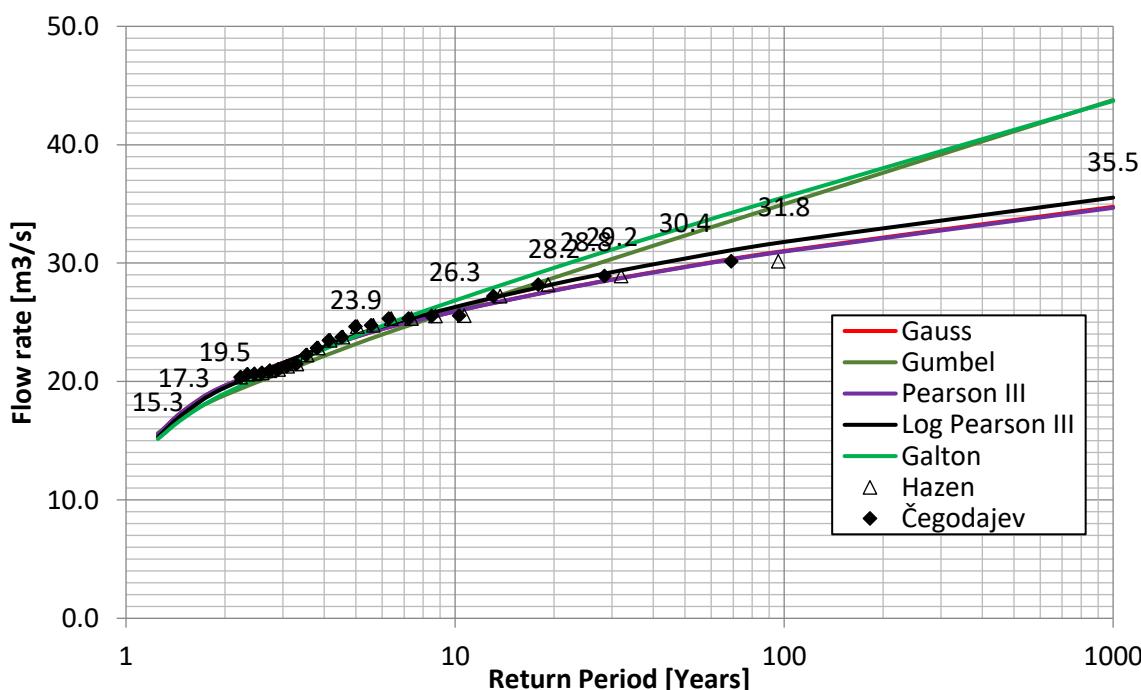

### 5.2.3.1.3 Flood frequency analysis from Amax series at gauge 16004 – Thurles

A Flood Frequency Analysis was conducted at station 16004 – Thurles for 49 years flood record (Figure 5.3) using four theoretical distributions: Gauss, Gumbel, Pearson III, Log Pearson III and Galton. Theoretical distributions were compared to the empirical distributions (Chegodaev and Hazen).

Log Pearson III distribution showed the best fit (see Figure 5.4) and was selected for the flow rate analysis for the site.

**Table 5.4. Flow frequency for gauge No 16004 Thurles.**

Flow rates Q [m <sup>3</sup> /s]						
Return Period [Years]	AEP [%]	Gauss	Gumbel	Pearson III	Log Pearson III	Galton
1000	0.10%	34.8	43.8	34.7	<b>35.5</b>	43.7
100	1.00%	31.0	35.0	31.0	<b>31.8</b>	35.6
50	2.00%	29.7	32.3	29.7	<b>30.4</b>	33.1
30	3.33%	28.6	30.4	28.6	<b>29.2</b>	31.2
25	4.00%	28.2	29.6	28.2	<b>28.8</b>	30.5
20	5.00%	27.7	28.8	27.7	<b>28.2</b>	29.6
10	10.00%	25.9	26.0	25.9	<b>26.3</b>	26.8
5	20.00%	23.8	23.2	23.8	<b>23.9</b>	23.8
2	50.00%	19.7	18.9	19.7	<b>19.5</b>	19.0
1.5	66.67%	17.6	17.1	17.6	<b>17.3</b>	16.9
1.25	80.00%	15.5	15.6	15.5	<b>15.3</b>	15.1

**Figure 5.4. Flood Frequency analysis for the EPA [3] gauge No 16004 Thurles.**

### 5.2.3.1.4 Adjusting 100-year flood for the proposed site

The flood frequency analysis showed the best fit for the Log Pearson III distribution (see Figure 9). The flood flows obtained for Log Pearson III distribution will be factorised to fit the location of the proposed bridge PC1 based on the catchment area.

The EPA gauge in Thurles has a catchment area of 228.7432km<sup>2</sup> and the bridge location for the site HEP east of Templemore has a contributing catchment area of 95.963km<sup>2</sup>. This means that all flows from the above flood frequency analysis should be factored with the following catchment area downscaling factor:

$$C_{\text{AREA}} = 95.963 / 228.7432 = \mathbf{0.419522854}.$$

**Table 5.5. Adjustment of flow rates for the proposed bridge location (factor 0.419522854 used).**

Flow rates Q [m <sup>3</sup> /s]			
Return Period [Years]	AEP [%]	Gauge No 16004 Location	Proposed Bridge Location
1000	0.10%	35.53	14.91
100	1.00%	31.79	13.34
50	2.00%	30.39	12.75
30	3.33%	29.23	12.26
25	4.00%	28.80	12.08
20	5.00%	28.23	11.85
10	10.00%	26.29	11.03
5	20.00%	23.93	10.04
2	50.00%	19.49	8.18
1.5	66.67%	17.31	7.26
1.25	80.00%	15.32	6.43

After the Climate Change Factor of 1.2 is applied;

**the frequency analysis gained 1% AEP flow of  $Q_{100cc}$  = 16.01m<sup>3</sup>/s.**

The design  $Q_{100cc}$  flows for all HEPs is shown in table below. Using similar downscaling factors the HEPs' flow rates were calculated as given in the table below.

**Table 5.6. Flood Frequency Analysis flows for HEPs –  $Q_{100cc}$ .**

Factorised Flow rates [m <sup>3</sup> /s]							
H1	H2	H3	H4	H5A	H5B	H6	H7
3.71	1.99	5.82	6.19	5.88	0.06	12.09	12.91
H8	H9	H10	H11	H12	H13	H14	H15
0.66	15.92	15.95	1.41	0.22	0.43	1.87	0.20
H16	H17	H18	H19	H20	H21	H22	H23
0.33	0.05	0.02	0.03	0.03	0.03	0.01	0.00
H24	H25	H26	H27				
0.10	0.06	0.00	0.04				

### 5.2.3.2 Flood Study Update

The catchment of the selected subject site has an area of more than 95km<sup>2</sup> which is above the FSU minimum threshold and is ideally suited for this catchment.

The FSU Catchment characteristic approach was used to determine Q<sub>med</sub> values. The OPW online tool was used to determine BFISOIL, SAAR, FARL, DRAIND, ARTDRAIN2 and URBEXT, see table below and [Annex K](#).

The site area is rural. Q<sub>med</sub> = 11.45 (2-year flood flow) was calculated based using equation below. A Climate Change factor of 1.20 is applied to the Q<sub>med</sub>.

$$Q_{med} = 1.237 \times 10^{-5} \text{ AREA}^{0.937} \text{ BFISOIL}^{0.922} \text{ SAAR}^{1.306} \text{ FARL}^{2.217} \text{ DRAIND}^{0.341} \text{ S1085}^{0.185} (1+\text{ARTDRAIN2})^{0.408} \quad (2.2)$$

$$Q_{med, urb} = Q_{med} \times (1+URBEXT)^{1.4825} \quad (2.3)$$

**Table 5.7. FSU Input parameters**

Contributing Catchment Area	see Table 1	km <sup>2</sup>
BFISOIL	0.5536

These flows were further processed for suitable form for hydraulic model input (see Table 5.12).

### 5.2.3.3 Hydrology – Summary

The catchment area was calculated to be 95km<sup>2</sup>.

The River Suir has a recording gauge at Thurles (EPA gauge 16004 - Thurles). A detailed Flood Frequency Analysis was conducted based on the 49 years of records. Based on the catchment area, the flow obtained from Flood Frequency Analysis was applied to the wind farm site.

In addition, FSU approach was used to determine Q<sub>med</sub>, Q<sub>100</sub>, Q<sub>100cc</sub> and Q<sub>1000cc</sub> flood flows.

The Flood frequency analysis of the observed data at Thurles station No 16004 is suggesting >50% lower flood flows when compared to FSU approach at the location of wind farm. To remain conservative, FSU approach was used. The design flows are shown in Table 5.11.

It should be noted that some of the sub-catchments have catchment area less than 25km<sup>2</sup>, thus input flow hydrographs are set to peak at the same time. This adds additional safety factor and implies that input flood flows flood maps are conservative.

**Table 5.10. Summary table comparing design Q<sub>100cc</sub> flows.**

## 5.3 HYDRAULIC MODEL FOR EXISTING RIVER SYSTEM

### 5.3.1 Methodology

The methodology described in Section above requires the development of a 1-D 2-D HEC-RAS computer model for varying flood flows to provide:

1. Hydrological/hydraulic simulations for the existing pre-development on the River Suir and flood plain site which give a benchmark for post-development impacts.
2. Hydrological/hydraulic simulations to determine if there are any hydrological/hydraulic impacts adjacent to or downstream of the site.
3. Hydrological/Hydraulic simulations of the initial proposed windfarm layout and iterations leading to the final design (chapter 6).
4. Hydrological/hydraulic simulations of the final windfarm layout to obtain all relevant data relating to the wind farm design and planning application.

### 5.3.2 Model description

The computer model is based on detailed river and tributary cross-sections which form the 1-D component of the model and detailed topographical maps of the surrounding flood plains which provide the 2-D component of the integrated 1D-2d HEC-RAS computer model. In addition to this, estimates of the river channel and flood plain roughness (Manning's-n values) are required as input parameters and these were determined during a site inspection.

Models were developed for two River Systems:

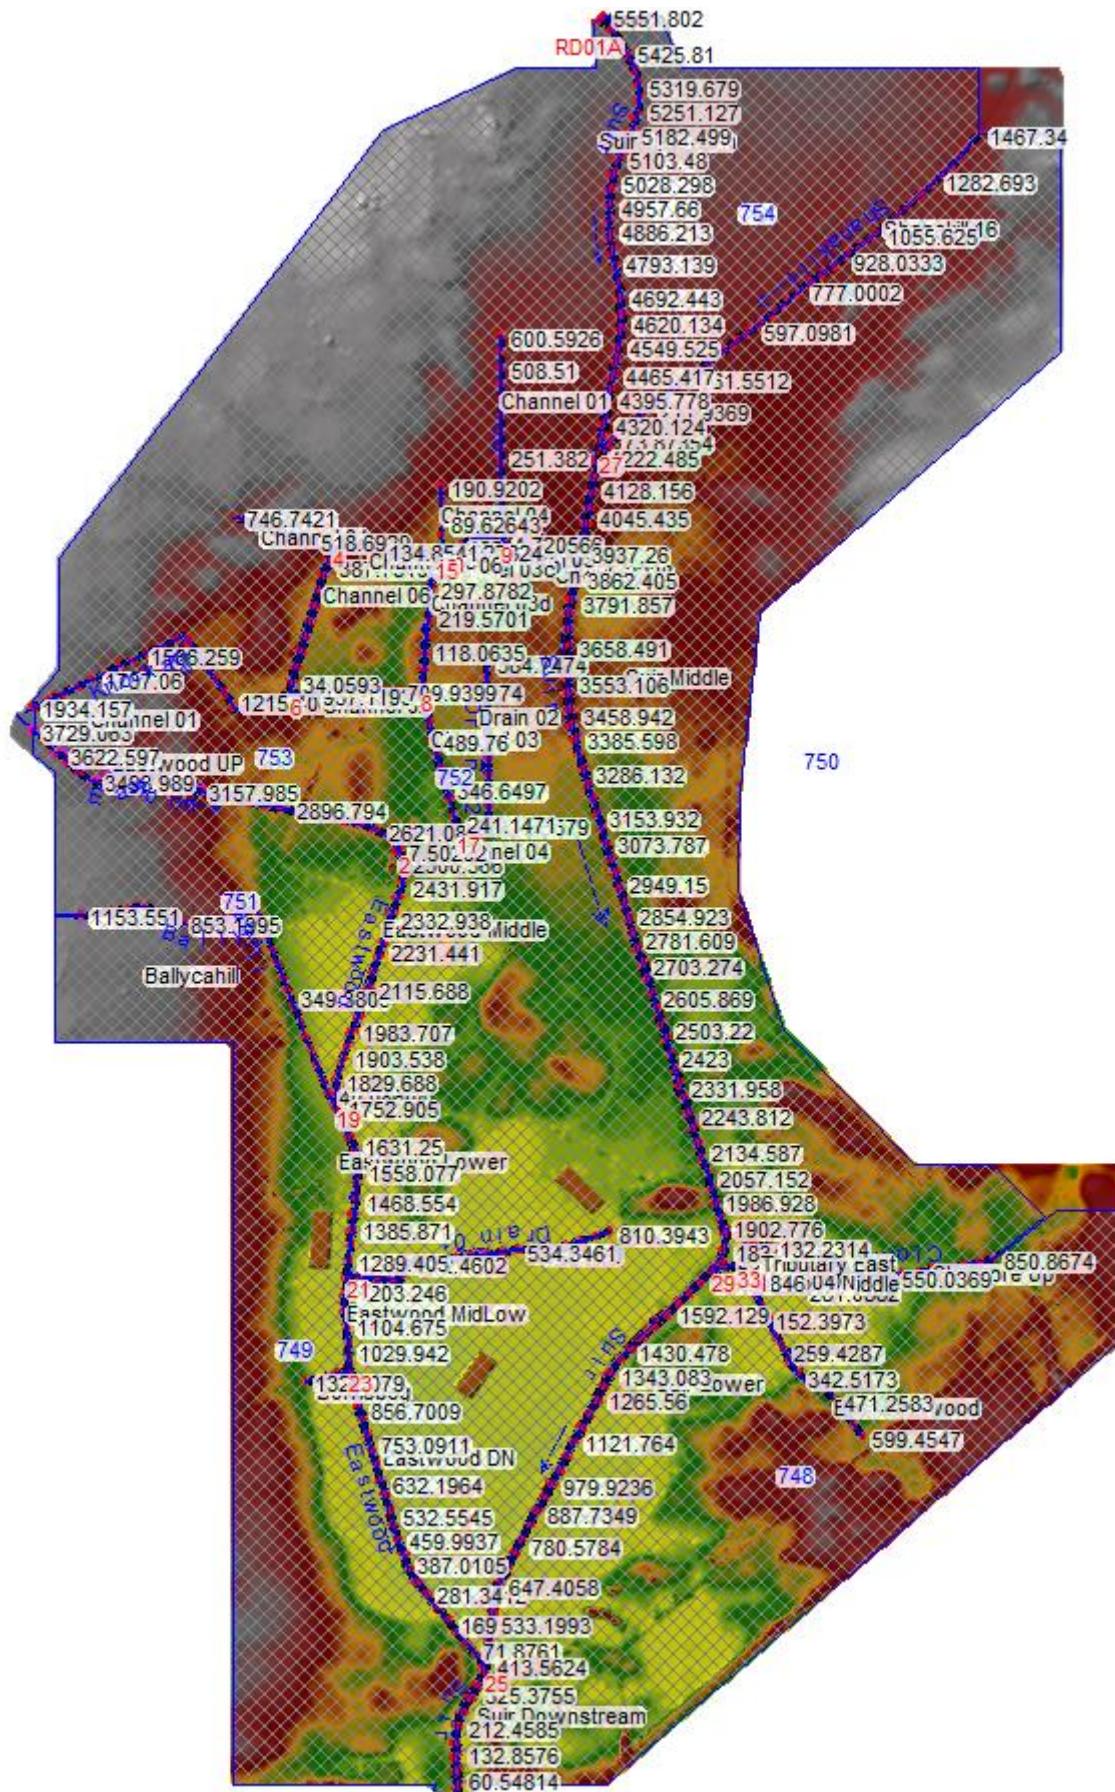

- Existing River System which uses the geometry of the natural river channel and flood plains.
- Design River System that includes the final geometry of the proposed windfarm.

In addition to the assessment of flood risks for the development, adjacent lands and downstream reaches, the simulations provided the following additional information:

- Identification of locations where new or upgraded culverts would be required.
- Identification of existing culverts and the role they play in providing storage in the hydrological system.

The 2D model covers an area of 10km<sup>2</sup>. The 1D model covers a reach of c. 16km, defined by 564 cross sections and a 25 bridges/culverts (the Existing River System model contains 22 bridges). The layout of the HEC-RAS cross-section locations and DTM are shown in Figure 10.

The model did not include any detail on the end masts. The impact of the masts was assessed during the site visit and it was concluded that the small footprint of the masts would not change the floodplain flow or storage in any significant way. The finished level of the roads covering the underground cable should be the same as the existing ground levels of the area in order to avoid disturbance of natural(existing) flow paths.

**Figure 10. Layout of HEC-RAS model.**

## 5.3.3 Model Input data

### 5.3.3.1 Geometry - Survey of river bed and flood plains

A survey of the river channel, banks and flood plains were carried out between 24<sup>th</sup> March 2022 to 1<sup>st</sup> April 2022 by KU217 Ltd. The survey included river banks, river channel and flood plains, (see Figure 5.5). The extensive area of the flood plains was surveyed using a LIDAR/RGB Drone surveying which was conducted by Maydon Ltd. The survey covered an area of approximately 1040ha and included a river length of more than 16km. The survey data were processed using a GIS toolset and a Digital Terrain Model (DTM) was created; two DTM's were created. The first DTM describes the Existing River System and flood plains (Figure 5.6) and second one describes the Design River System with added wind turbine hardstands elevated above flood water levels, a road network which follows the existing terrain and includes additional bridges and culverts (Figure 6.1).

Figure 5.5. Overlay of the Survey points and satellite images.

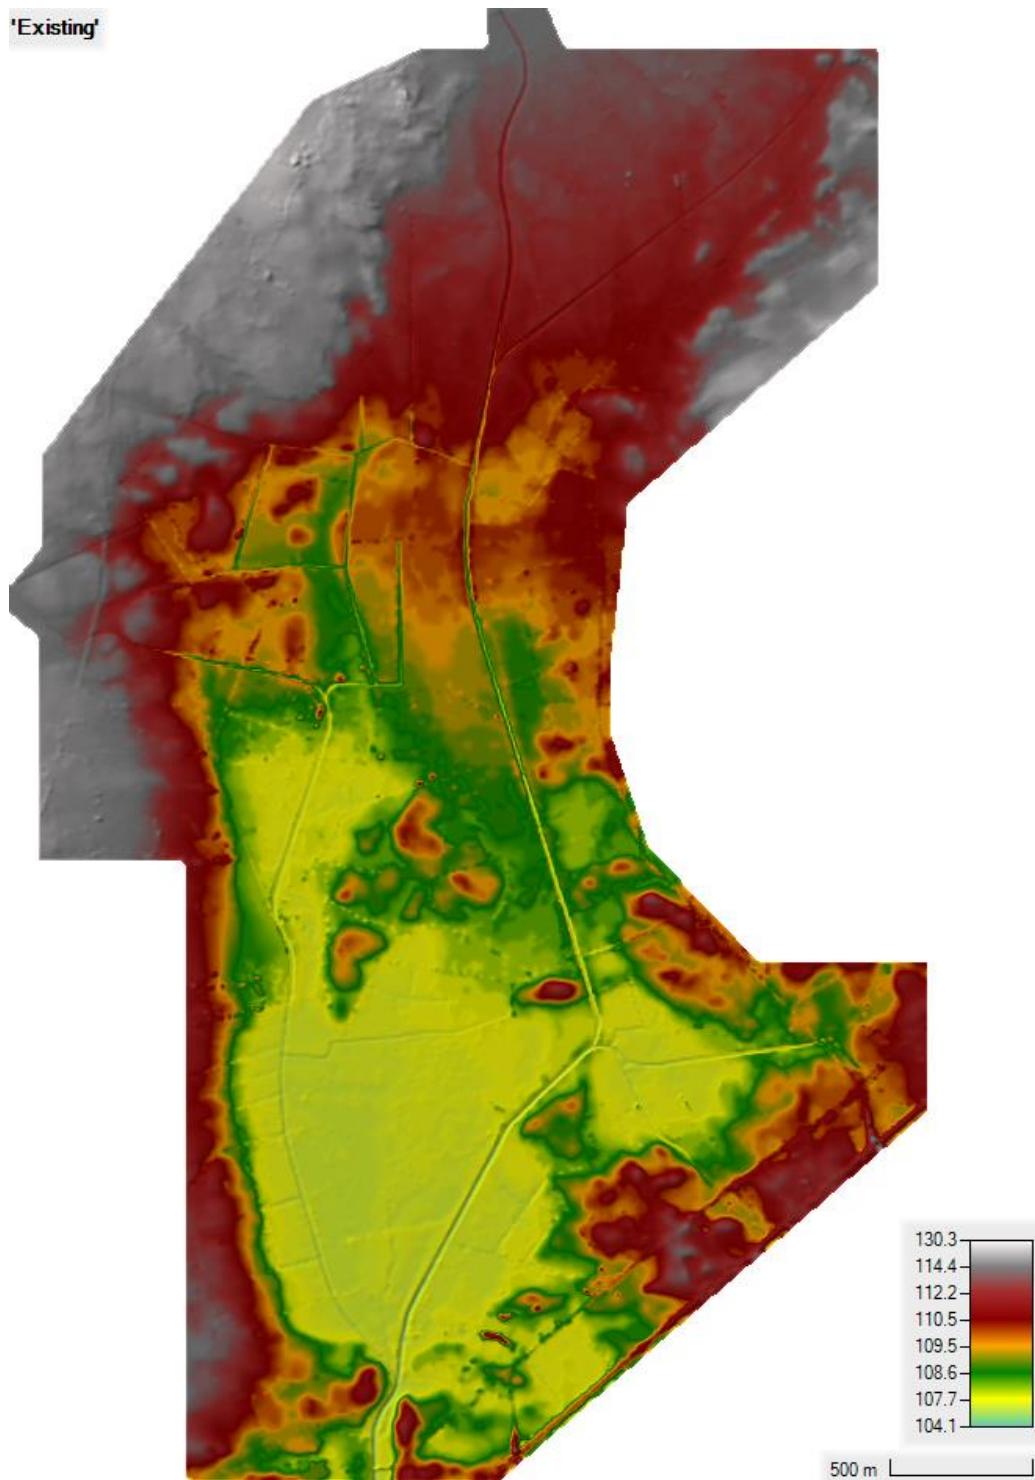

Figure 5.6. Digital Terrain Model of the existing model area.

### 5.3.3.2 Upstream Boundary condition

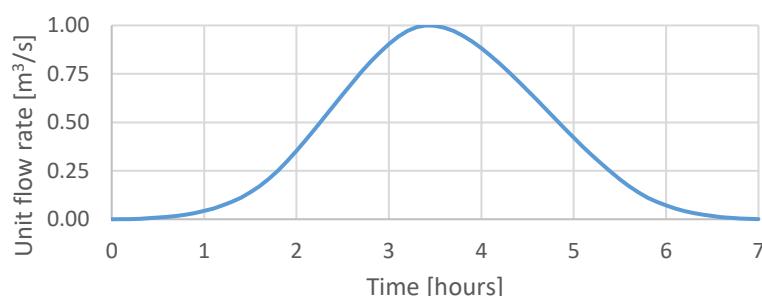

The upstream boundary condition is defined with a 7-hour hydrograph with a 3.4-hour rising stages (see Figure 5.7). A total of 21 upstream boundary conditions were defined and are listed in Table 5.12.

**Table 5.12. Input design flows for the hydraulic model.**

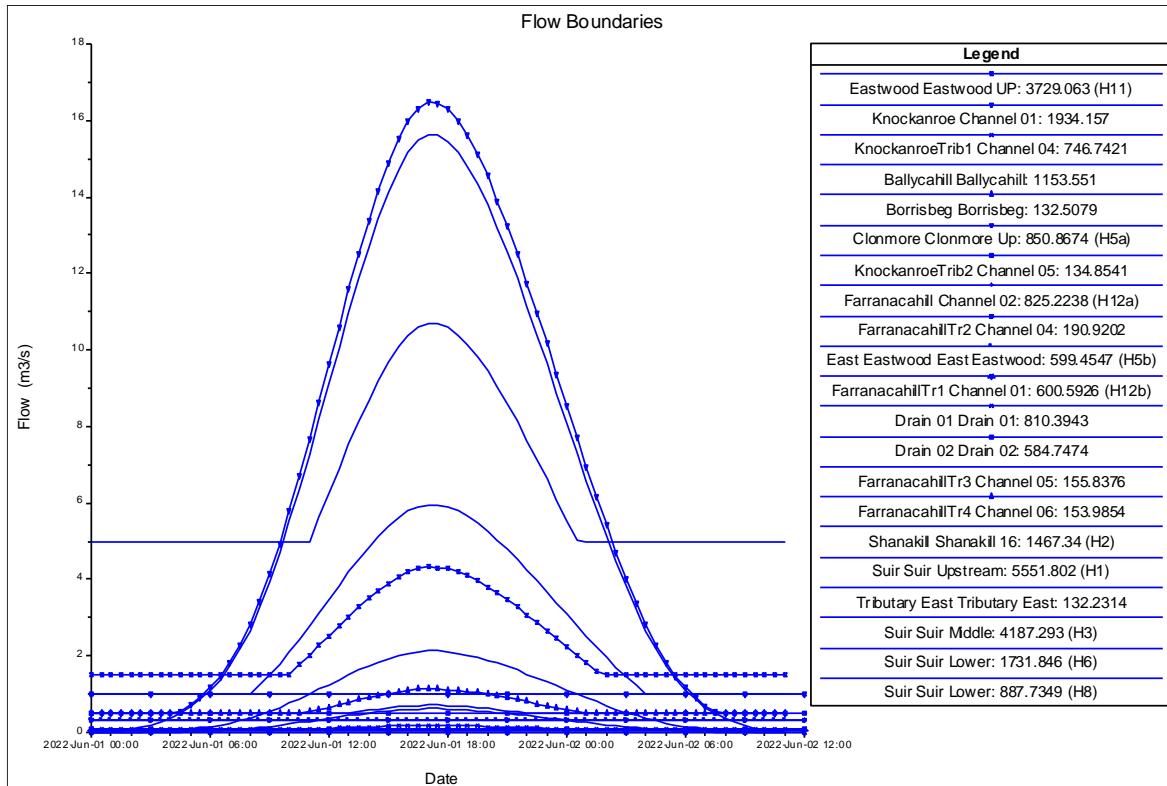

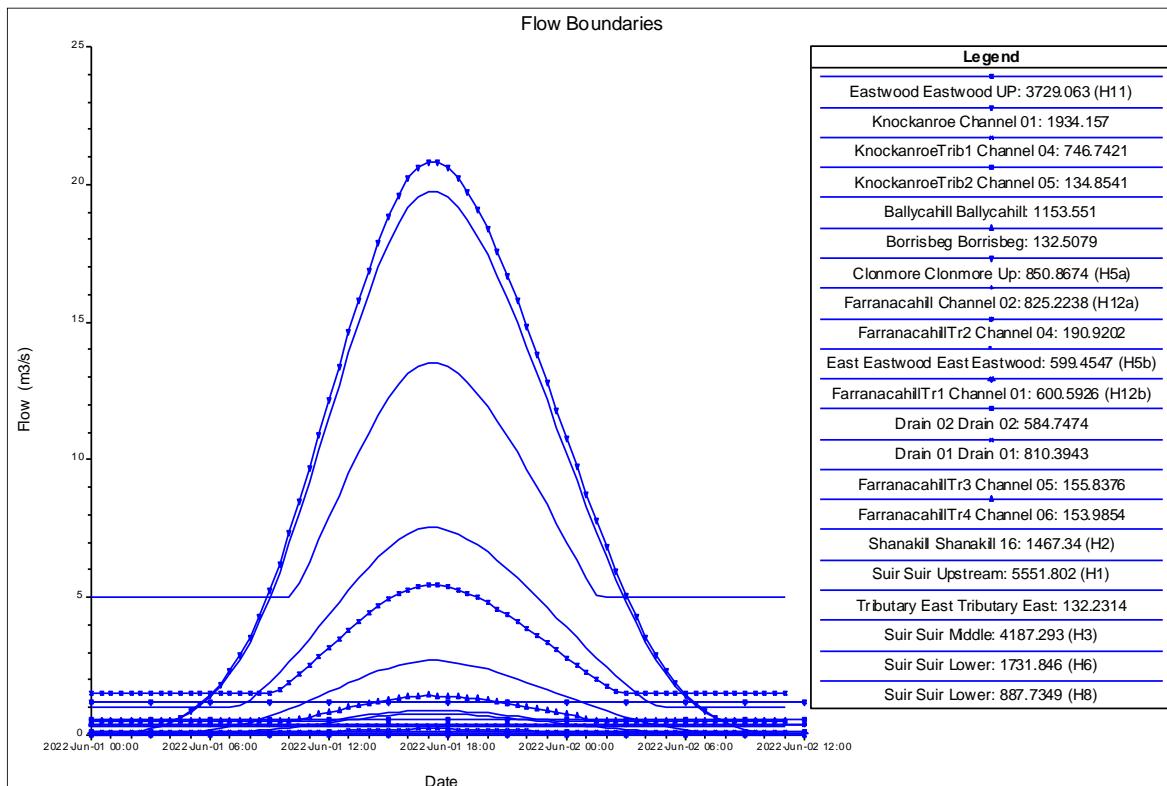

HEPs	HEC-RAS				Peak Flow [m <sup>3</sup> /s]

H27	22	East Tributary	East Tributary	132.2314	0.04	0.14

\*Note that for model stability higher peak flow than 0.3m<sup>3</sup>/s was used

Unit hydrographs were multiplied with peak flows from Table 5.12 to obtain the final shapes of the input hydrographs. All input hydrographs for Q<sub>med</sub> and Q<sub>100cc</sub> are shown in Figure 5.8 and Figure 5.9 respectively.

**Figure 5.7. Unit hydrograph.**

**Figure 5.8. Resulting hydrographs for  $Q_{100cc}$ .****Figure 5.9. Resulting hydrographs for  $Q_{100cc}$ .**

### 5.3.3.3 Downstream Boundary condition

The downstream boundary conditions are defined as the normal depth,  $d_n$ , with a defined energy slope of 0.008m/m.

### 5.3.3.4 Calibration results

According to inspected site conditions, **roughness values for river channel have a Manning coefficient of  $n=0.045 - 0.050 \text{ s/m}^{1/3}$ . Roughness factor of  $n=0.060 \text{ s/m}^{1/3}$  was used for the flood plains.** Recommended values of Manning roughness values for channels and flood plains are shown in [Annex E - Table E4.3](#).

## 5.3.4 Design events in flood risk scoping

Using the HEC-RAS computer model, computer simulations were carried out for unsteady flow conditions using a flood flow value corresponding to the peak of the flood hydrograph. In summary the flood risk at development site was analysed for two hydrologically extreme existing scenarios, as shown in Table 5.13.

**Table 5.13. Design Events used in flood risk scoping**

Design event	Flow Rate [ $\text{m}^3/\text{s}$ ] / return period	Downstream boundary condition – Normal depth	Description
1	$Q_{100\text{cc}}$ (20% climate change)	0.008m/m.	<b>Flood zone A - <math>Q_{100\text{cc}}</math>-Exist</b>
2	$Q_{1000\text{cc}}$ (20% climate change)	0.008m/m.	<b>Flood zone B - <math>Q_{1000\text{cc}}</math>- Exist</b>

## 5.3.5 Computer model results for existing river system

The results are shown for Existing River System for  $Q_{100\text{cc}}$  and  $Q_{1000\text{cc}}$  year flow rates with included 20% increase of flows due to climate change (MRFS) as follows:

- $Q_{100\text{cc}}$  and  $Q_{1000\text{cc}}$  Longitudinal profiles for River Suir main channel showing water levels for Existing river system (Figure 5.10).
- $Q_{100\text{cc}}$  and  $Q_{1000\text{cc}}$  Longitudinal profiles for Eastwood tributary showing water levels for Existing river system (Figure 5.11).
- $Q_{100\text{cc}}$  and  $Q_{1000\text{cc}}$  Flow velocity map for the River Suir main channel for Existing River System (Figure 5.12).
- $Q_{100\text{cc}}$  and  $Q_{1000\text{cc}}$  Flow velocity map for the Eastwood tributary channel for Existing River System (Figure 5.13).
- $Q_{100\text{cc}}$  Flow velocity maps for Existing river system (Figure 8.1).
- $Q_{1000\text{cc}}$  Flow velocity maps for Existing river system (Figure 8.2).
- $Q_{100\text{cc}}$  Flood Maps for Existing river system (Figure 8.3).
- $Q_{1000\text{cc}}$  Flood Maps for Existing river system (Figure 8.4).

Table output model results for  $Q_{100\text{cc}}$  (MRFS) and  $Q_{1000\text{cc}}$  (HEFS) is shown in Annex H.

### 5.3.5.1 Longitudinal profiles

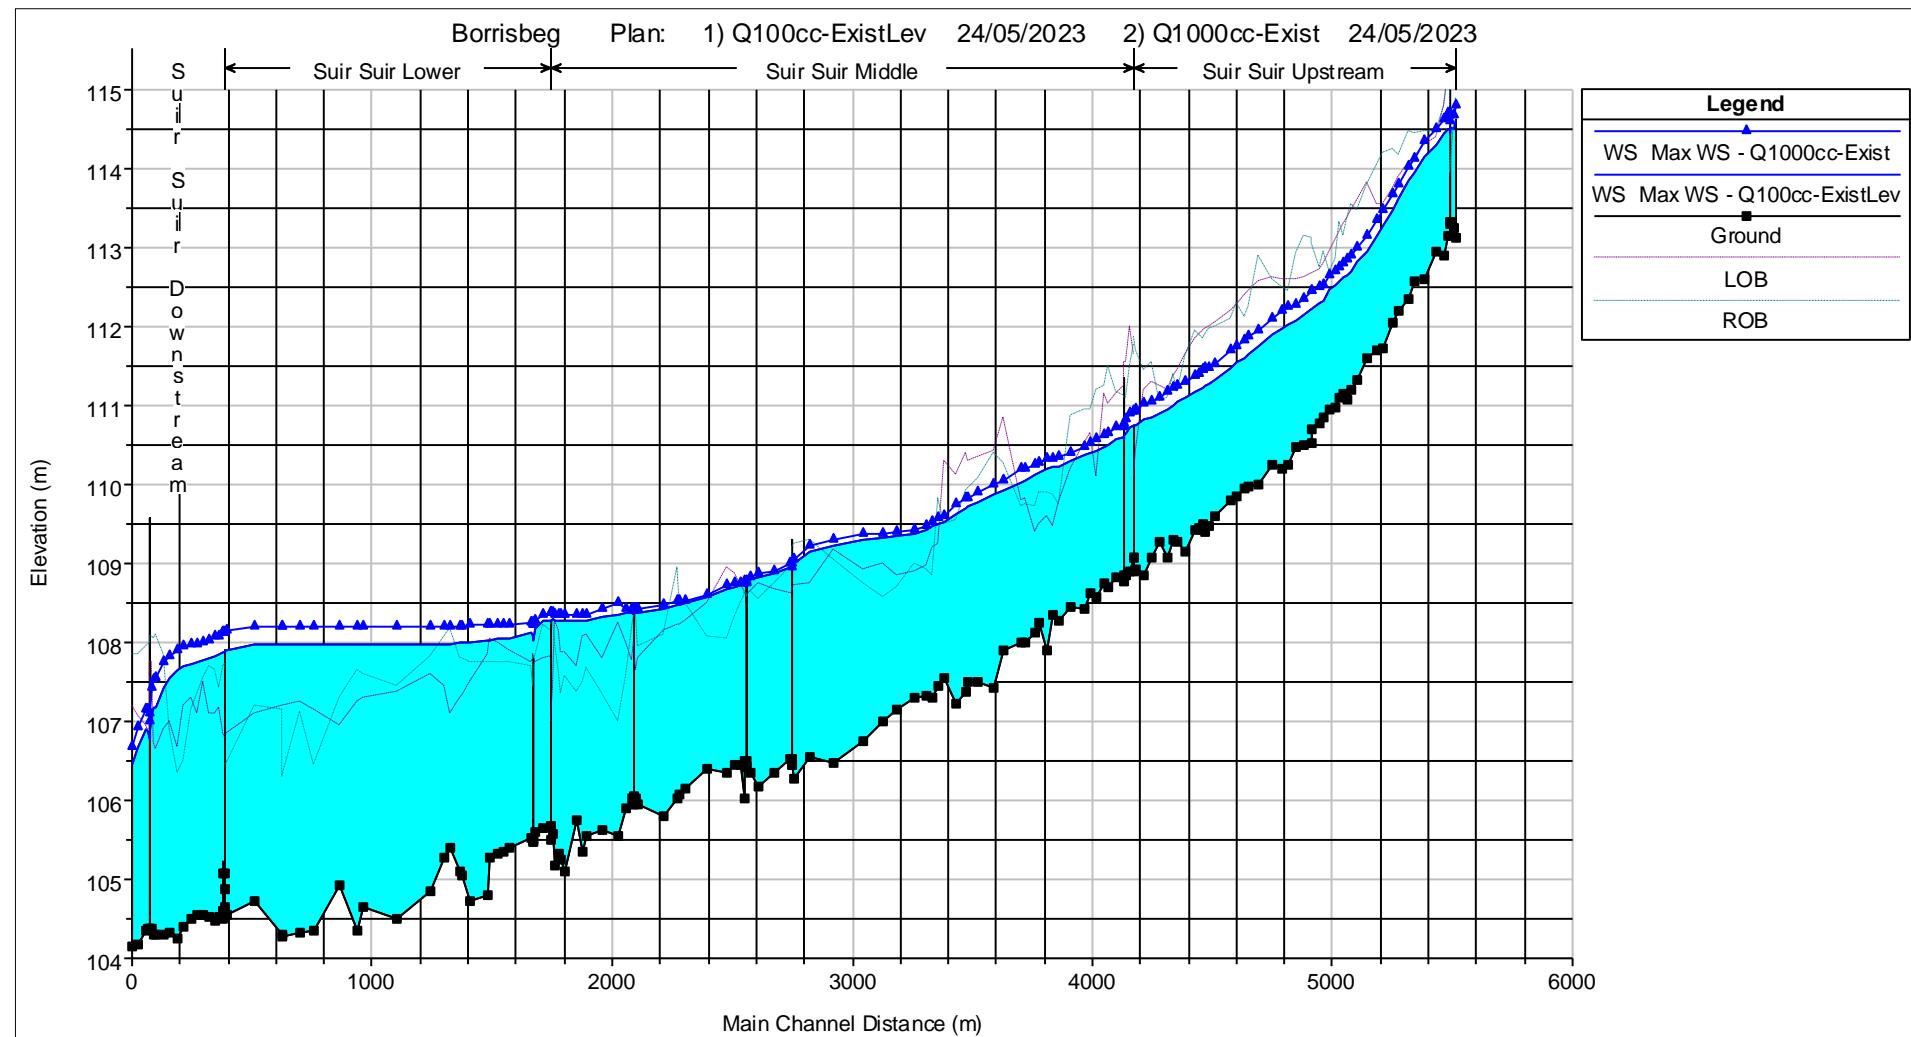

Figure 5.10. Suir Longitudinal profile showing water levels in the river channel for Existing River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

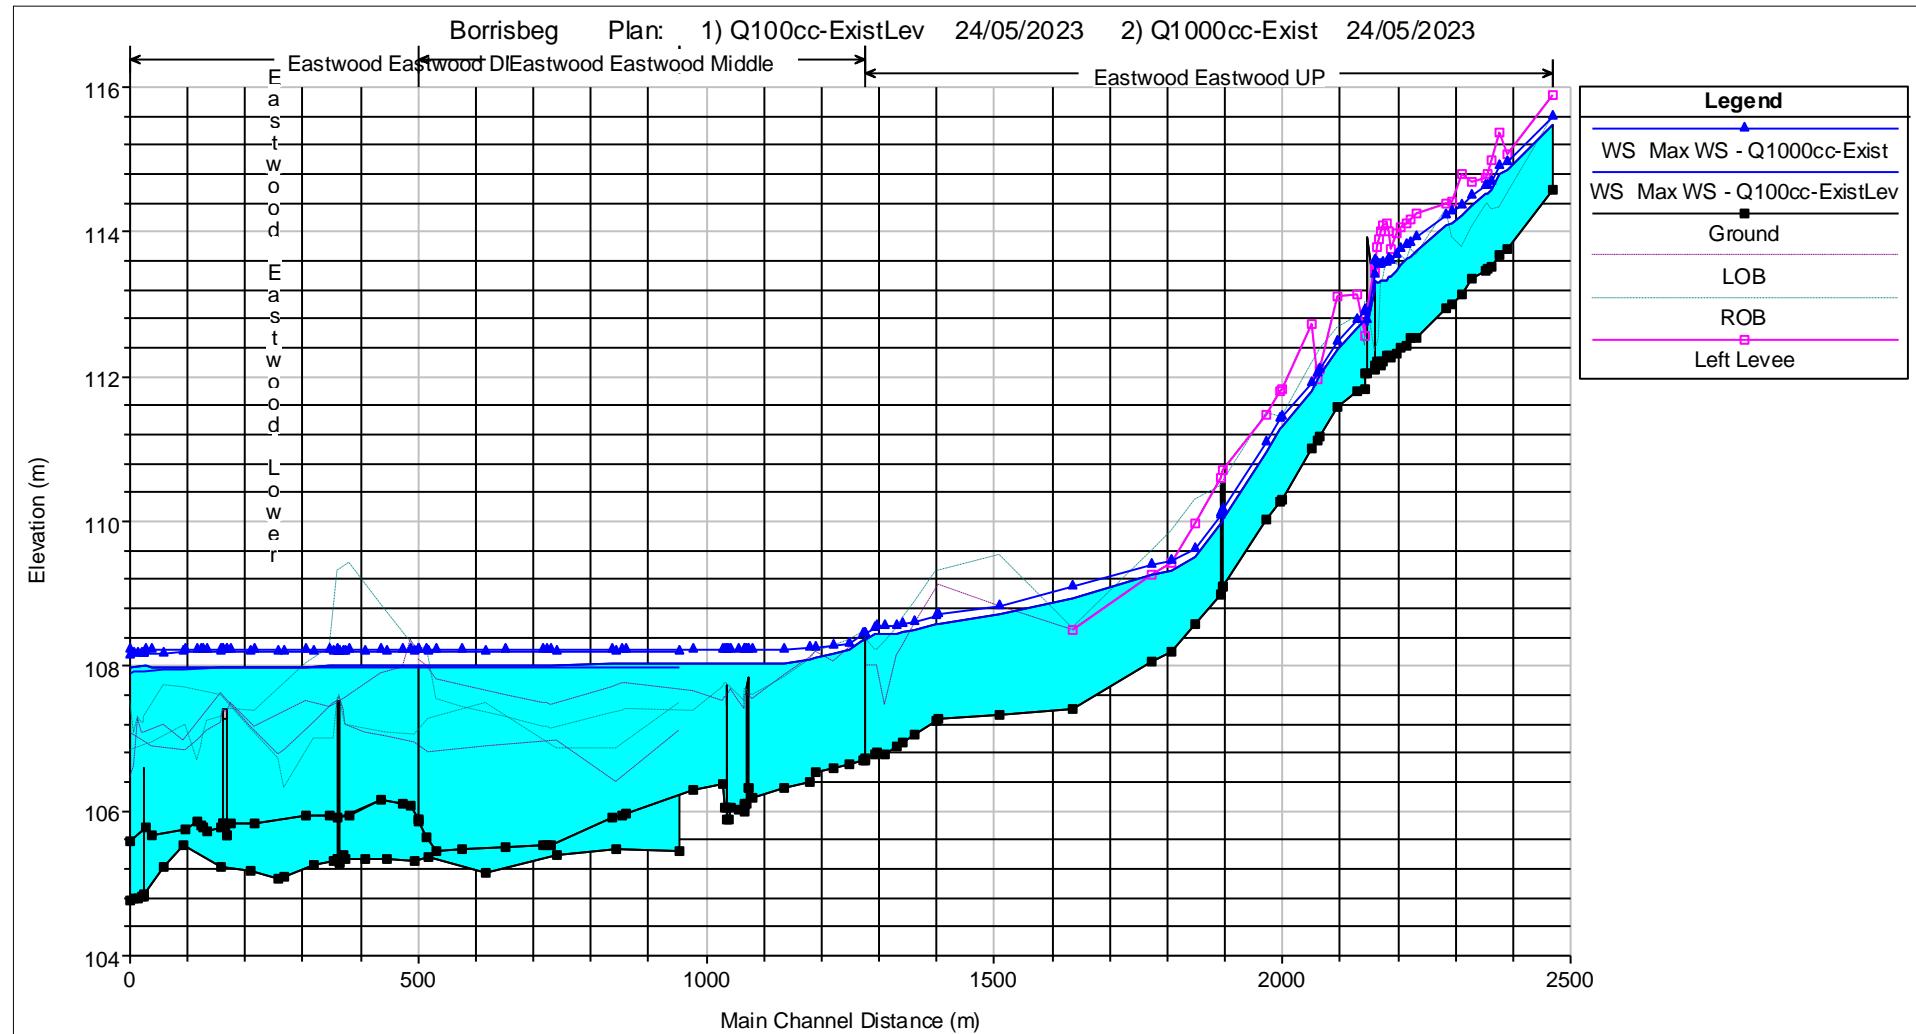

Figure 5.11. Eastwood Longitudinal profile showing water levels in the river channel for Existing River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

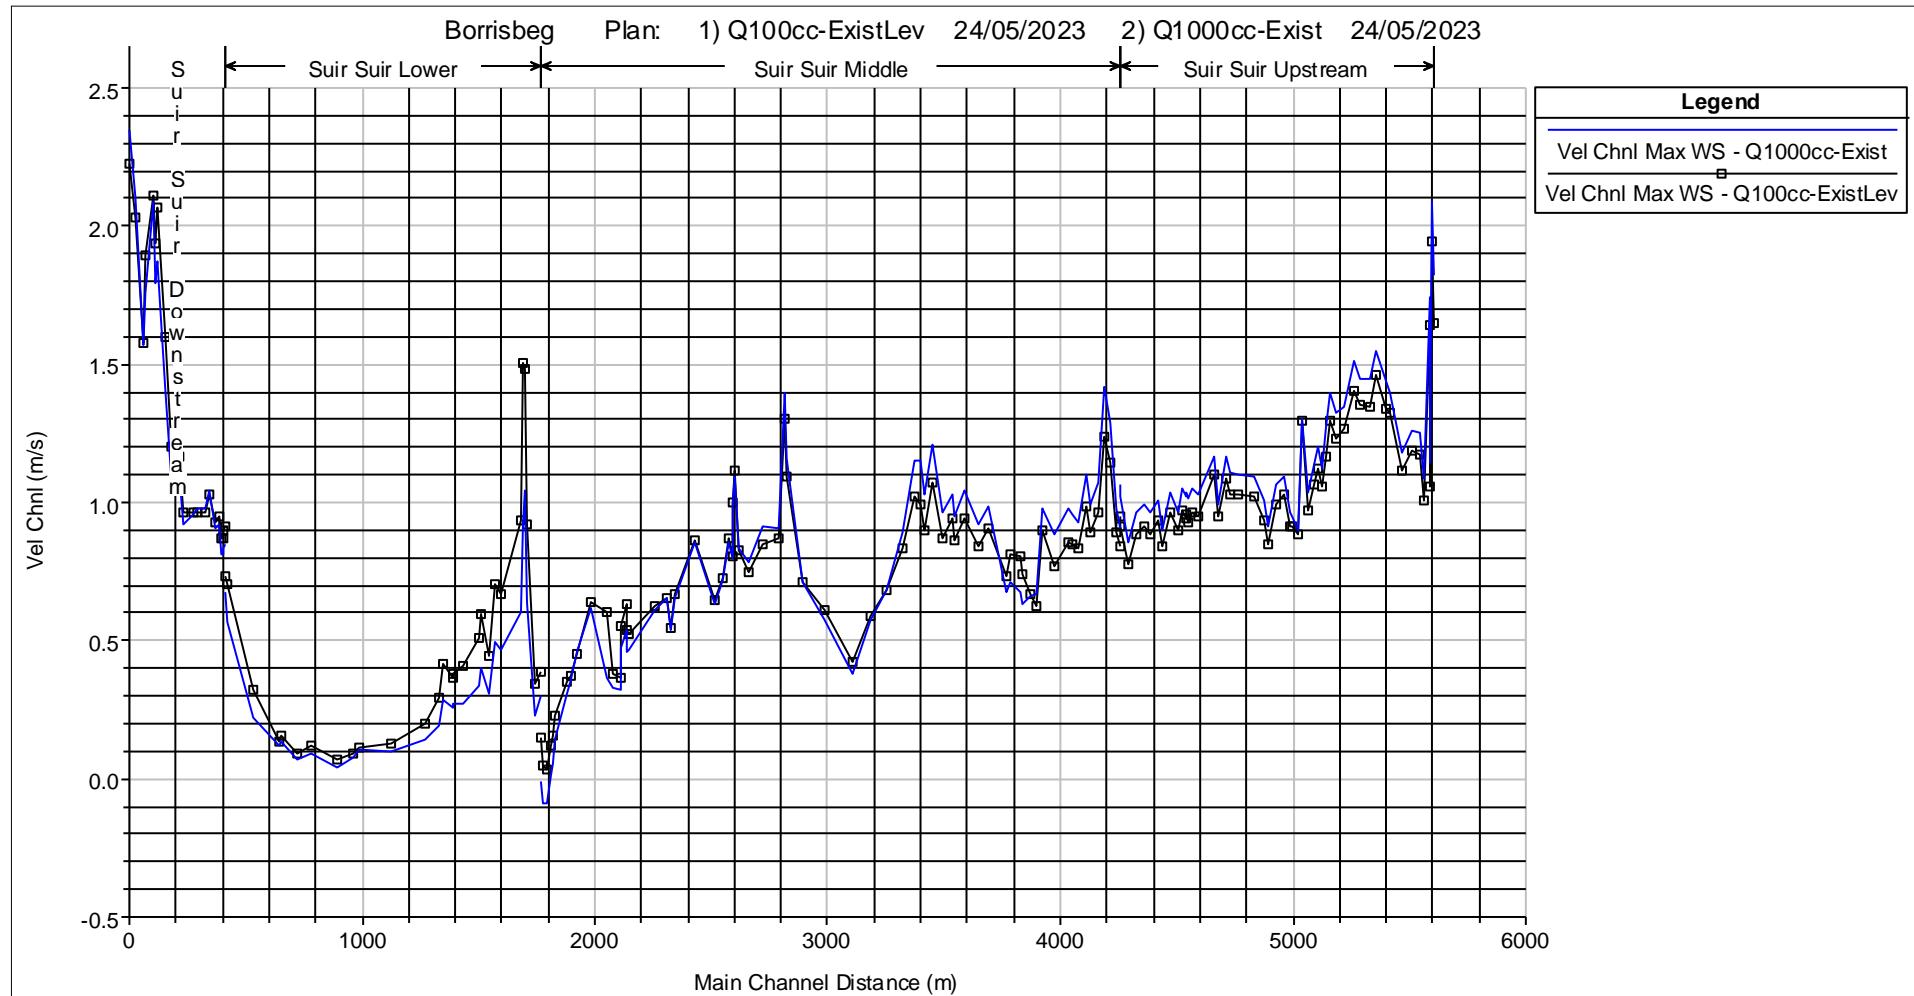

Figure 5.12. Suir Longitudinal profile showing flow velocity in the river channel for Existing River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

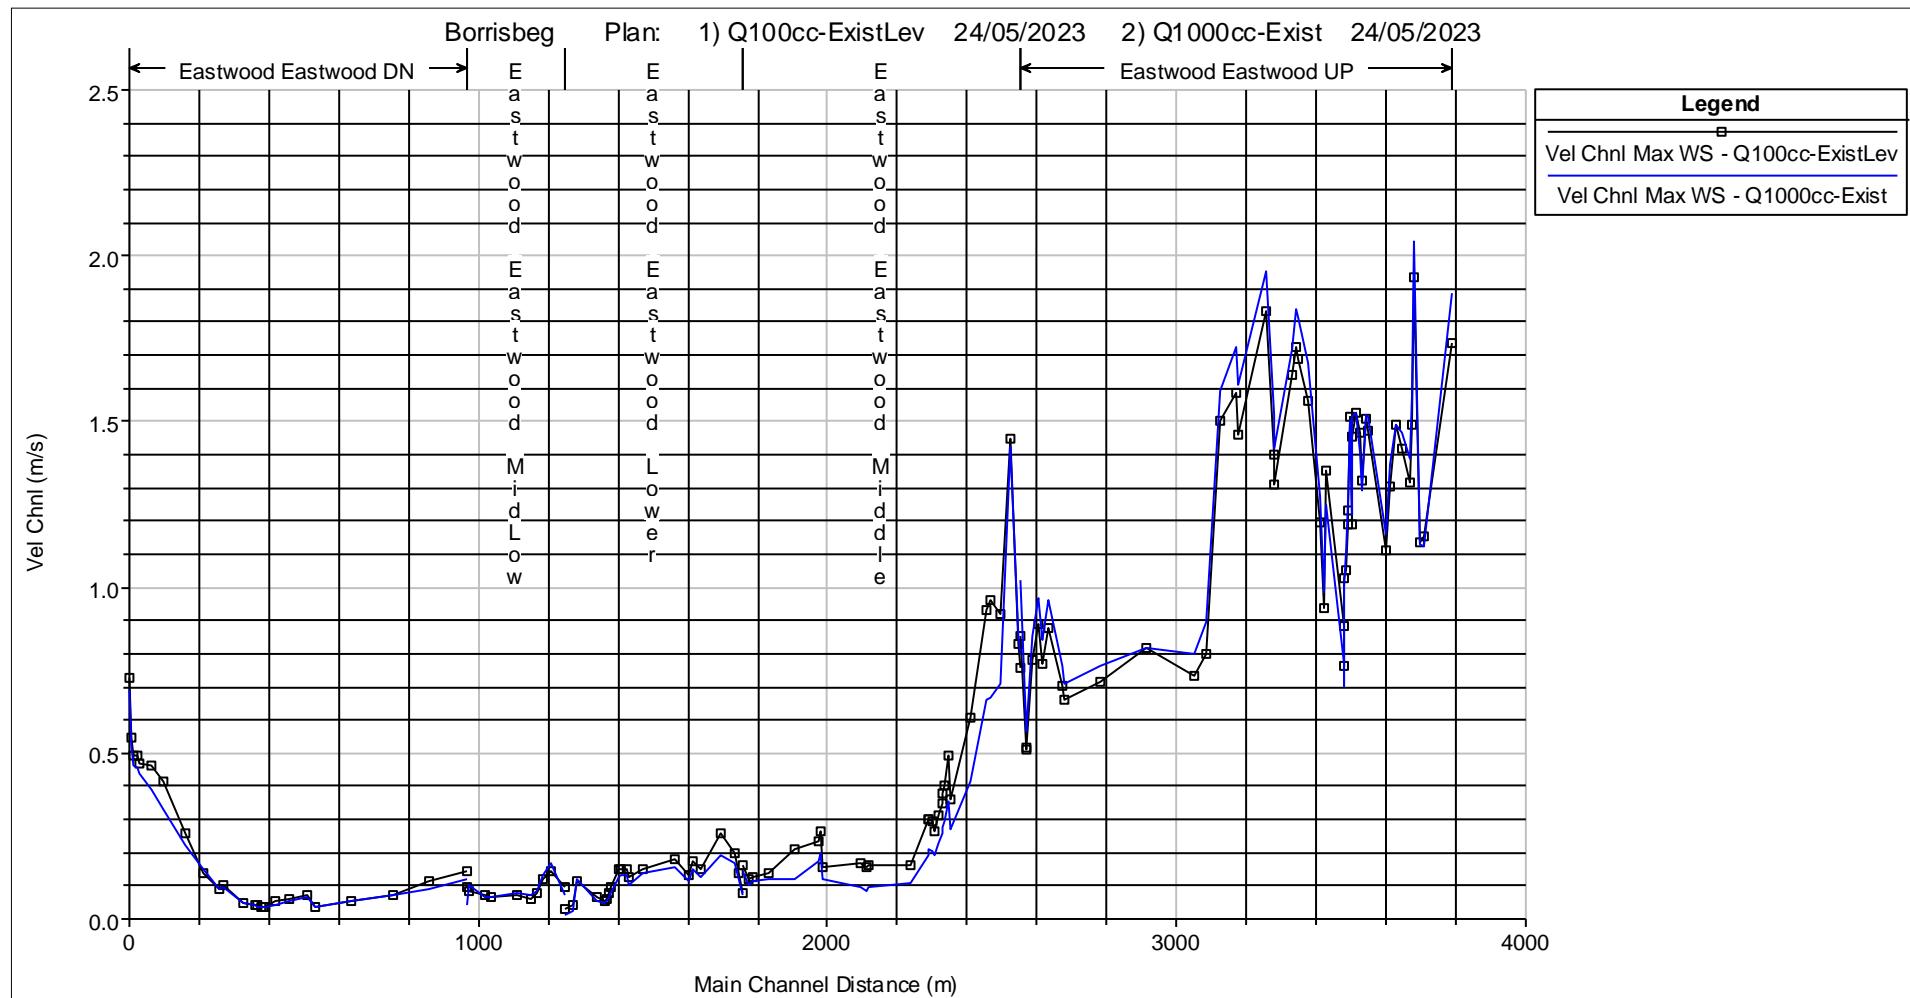

Figure 5.13. Eastwood Longitudinal profile showing flow velocity in the river channel for Existing River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

## 5.4 FLOOD RISK MANAGEMENT MEASURES

### 5.4.1 Fluvial and coastal flood risk

#### Finished Floor/Hardstand Levels

In order to mitigate tidal and fluvial flood risk, the proposed properties, e.g. wind turbine hard stands and substation should be constructed with their finished floor/ground levels at a height greater than:

$$(1000\text{-year flood flow including climate change}) + \text{c. } 0.5\text{m}$$

Design Finished Floor Levels are shown in Table 6.3.

#### Site roads

The finished level of site roads should be the same as the existing ground levels of the site in order to avoid disturbance of natural(existing) flood flow paths.

#### Bridges and Culverts

Proposed bridges and culverts or culvert upgrades should be constructed in compliance with OPW Section 50.

### 5.4.2 Coastal flooding

Excluded from further investigation. See section 4.3.2.

### 5.4.3 Pluvial flooding

Some pounding evident, but affects soil conditions rather than causing flooding. Excluded from further investigation. See section 4.3.3.

### 5.4.4 Overland flooding

Excluded from further investigation. See section 4.3.4.

### 5.4.5 Groundwater flooding

Excluded from further investigation. See section 4.3.5.

### 5.4.6 Drainage systems

Excluded from further investigation and attributed to fluvial flooding. See section 4.3.6.

## 6 Stage 3 – Detailed flood risk assessment

### 6.1 INTRODUCTION

This detailed risk assessment assesses the combined effects of the two rivers, the Suir and the Eastwood and a network of field drainage channels at the development site. Residual risks that remain after all risk avoidance, substitution and mitigation measures have been applied, have also been considered. An iterative process of the assessment of flood risk and impacts has been performed, to give detailed design parameters which are recommended for the wind farm development.

The hydrology of the system is calculated and elaborated on in Chapter 5 and section 5.2.3. Two flow rate scenarios combining climate change (20% flow increase) were analysed in order to obtain flood Zones A and B, in accordance with Table 5.13 and Table 6.1.

In order to examine the extreme hydrological occurrence of ‘worst case scenario’ the approach of combining all flow hydrographs peaks simultaneously is used and is considered conservative.

#### 6.1.1 Risk of fluvial flooding

The Stage 1 assessment concluded that the development proposal is at risk from river, e.g. fluvial flooding, and that the proposed development site falls in flood Zone A and Zone B.

In the scoping process, additional detail surveys have been conducted and subsequently computer model simulations were performed for the existing river system. An assessment of proposed mitigation measures for river flood risk involved computer simulations to determine flood levels at the site for the river channel and modified floodplain.

#### 6.1.2 Risk of coastal flooding

The Stage 1 assessment concluded that the development proposal is not at risk of coastal flooding (see 4.3.2).

#### 6.1.3 Risk of pluvial flooding

The Stage 1 assessment concluded that the development proposal is not at risk of pluvial flooding (see 4.3.3).

#### 6.1.4 Risk of artificial drainage system and groundwater flooding

It was concluded that the development site is at low risk of flooding from artificial drainage systems and groundwater flooding, and therefore these flood mechanisms were excluded from risk assessment. See section 4.3.4. and section 4.3.5.

#### 6.1.5 Surface water drainage risk

The study also examines the effect of the proposed development on the storm runoff from the site area and assesses if this will have any significant impact on flood levels in the rivers. Since extreme flood levels are dominated by extreme river levels the contribution from surface runoff from a relatively small site will be insignificant. Therefore, it is excluded from further investigation.

#### 6.1.6 Risk of flooding due to culvert blockage

A tree investigation was conducted on site in order to determine if there is a risk of blockage at the culverts due to fallen trees (Table 3.1). There is some risk for four culverts to be blocked (due to small pipe diameter of 600mm). Culvert 16 is already partially blocked due to partial collapse of its stone opening. Culverts 12, 14 and 15 are under of risk of blockage due to their small size (600mm).

## 6.2 HYDRAULIC MODEL FOR DESIGN RIVER SYSTEM

### 6.2.1 Model Input data

The Design Model input data is a combination of Existing River System model data, (see section 5.3.3 for input Digital Terrain Model data), and the additional geometry of nine turbine hardstands and three bridges which are required for windfarm access road (Figure 6.1).

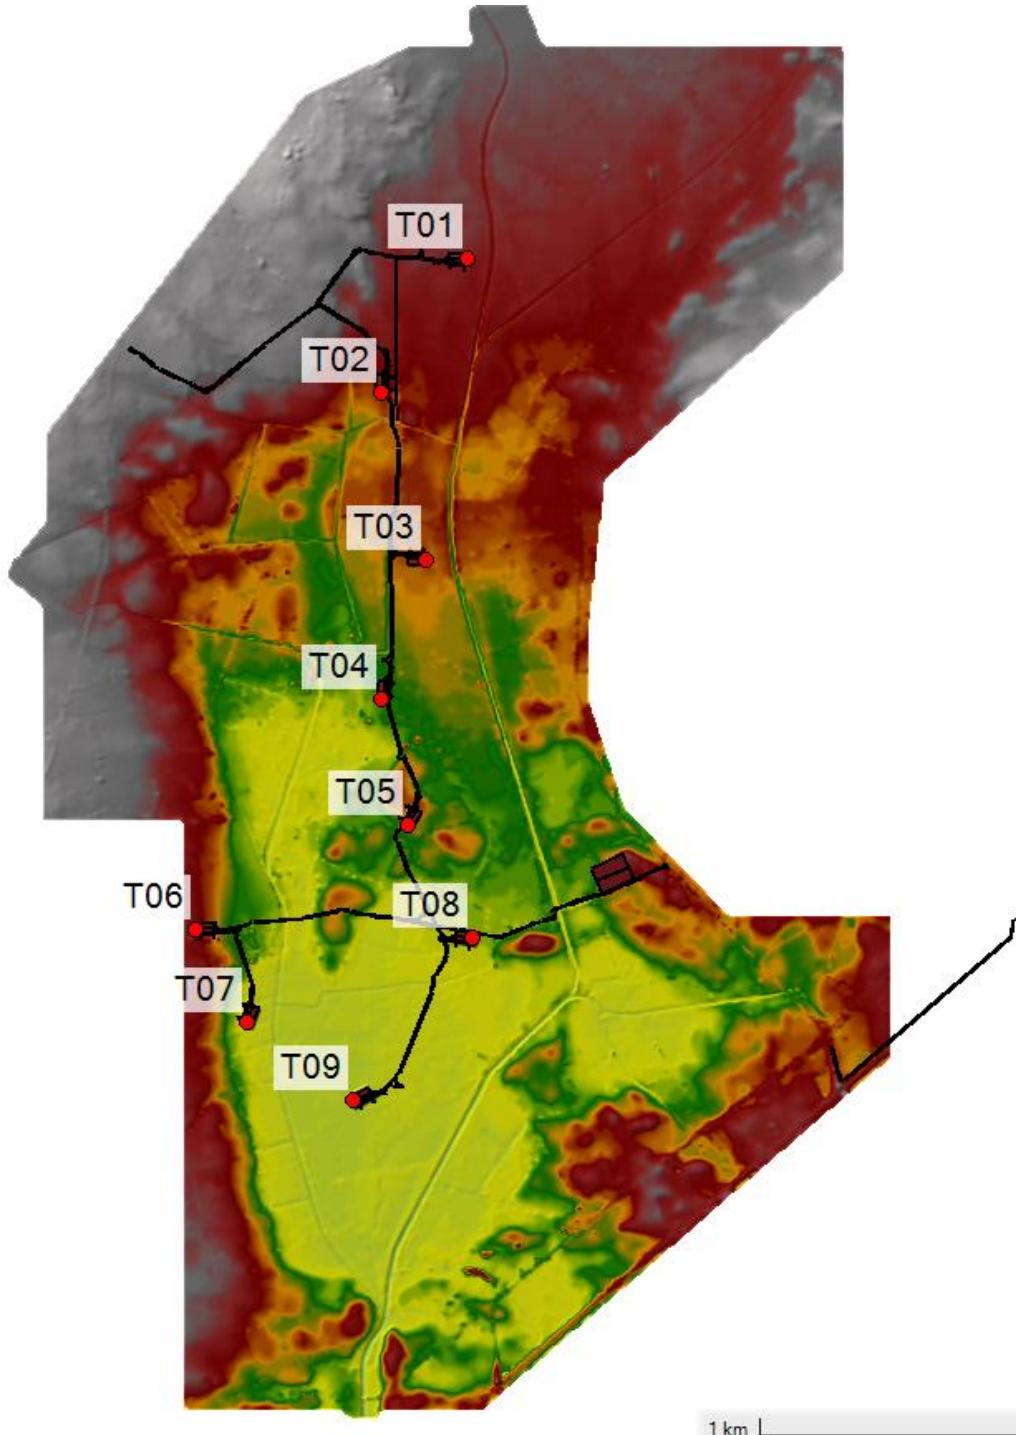

Figure 6.1. Digital Terrain Model of the design model area.

## 6.2.2 Design events in flood risk scoping

Using the HEC-RAS computer model, computer simulations were carried out for unsteady flow conditions using a flood flow value corresponding to the peak of the flood hydrograph. In summary the flood risk at development site was analysed for two hydrologically extreme design scenarios, as shown in Table 6.1.

**Table 6.1. Design Events used in flood risk scoping**

Design event	Flow Rate [m <sup>3</sup> /s] / return period	Downstream boundary condition – Normal depth	Description
1	Q <sub>100cc</sub> (20% climate change)	0.008m/m.	<b>Flood zone A - Q<sub>100cc</sub>-Design</b>
2	Q <sub>1000cc</sub> (20% climate change)	0.008m/m.	<b>Flood zone B - Q<sub>1000cc</sub>-Design</b>

## 6.2.3 Computer model results for design river system

The results are shown for Existing River System for Q<sub>100cc</sub> and Q<sub>1000cc</sub> year flow as follows:

- Q<sub>100cc</sub> and Q<sub>1000cc</sub> Longitudinal profiles for River Suir main channel showing water levels for Design river system (Figure 6.2).
- Q<sub>100cc</sub> Longitudinal profiles for River Suir main channel showing water levels for Existing and Design river system (Figure 6.3).
- Q<sub>1000cc</sub> Longitudinal profiles for River Suir main channel showing water levels for Existing and Design river system (Figure 6.4).
- Q<sub>100cc</sub> and Q<sub>1000cc</sub> Longitudinal profiles for Eastwood tributary showing water levels for Design river system (Figure 6.5).
- Q<sub>100cc</sub> Longitudinal profiles for Eastwood tributary showing water levels for Existing and Design river system (Figure 6.6).
- Q<sub>1000cc</sub> Longitudinal profiles for Eastwood tributary showing water levels for Existing and Design river system (Figure 6.7).
- Q<sub>100cc</sub> and Q<sub>1000cc</sub> Flow velocity profile for the River Suir main channel for Existing and Design River Systems (Figure 6.8).
- Q<sub>100cc</sub> and Q<sub>1000cc</sub> Flow velocity profile for the Eastwood tributary channel for Existing and Design River Systems (Figure 6.9).
- Q<sub>100cc</sub> Flow velocity distribution maps for Design river system (Figure 8.5).
- Q<sub>1000cc</sub> Flow velocity distribution maps for Design river system (Figure 8.6).
- Q<sub>100cc</sub> Flow depth maps for Design river system (Figure 8.7).
- Q<sub>1000cc</sub> Flow depth maps for Design river system (Figure 8.8).
- Flood zone A Existing and Design river system comparison (Figure 8.9).
- Flood zone B Existing and Design river system comparison (Figure 8.10).
- Flood zone A Comparison of Water Levels for Existing and Design river system (Figure 8.9).
- Flood zone B Comparison of Water Levels for Existing and Design river system (Figure 8.10).
- Hydrographs for Existing and design river systems to ascertain if there has been any change in the downstream flow as a result of the wind farm development (Figure 6.17).

Table output model results for Q<sub>100cc</sub> (MRFS) and Q<sub>1000cc</sub> (HEFS) is shown in Annex H.

## 6.2.4 Longitudinal profiles

There are two main river channels within the zone of influence of the wind farm. The main River Suir channel and the Eastwood tributary channel. Figure 6.2 below, for the main River Suir channel, gives the longitudinal profiles for the  $Q_{100cc}$  and  $Q_{1000cc}$  flows for Final Design River System - one superimposed on the other.

Comparison of water levels between Existing and Design river systems - one superimposed on the other is shown in Figure 6.3 and Figure 6.4 for the main River Suir channel for  $Q_{100cc}$  and  $Q_{1000cc}$  respectively. It is clear that the two water surface profiles are co-incident which confirms that the construction of the wind farm involving access roads and turbine hardstands has no impact on the water levels for the extreme  $Q_{100cc}$  and  $Q_{1000cc}$  flood events.

Figure 6.6 and Figure 6.7 show water level longitudinal profiles for  $Q_{100cc}$  and  $Q_{1000cc}$  respectively for the Eastwood channel and again the surface profiles are co-incident for the existing and Design River Systems confirming no water level change due to the windfarm construction.

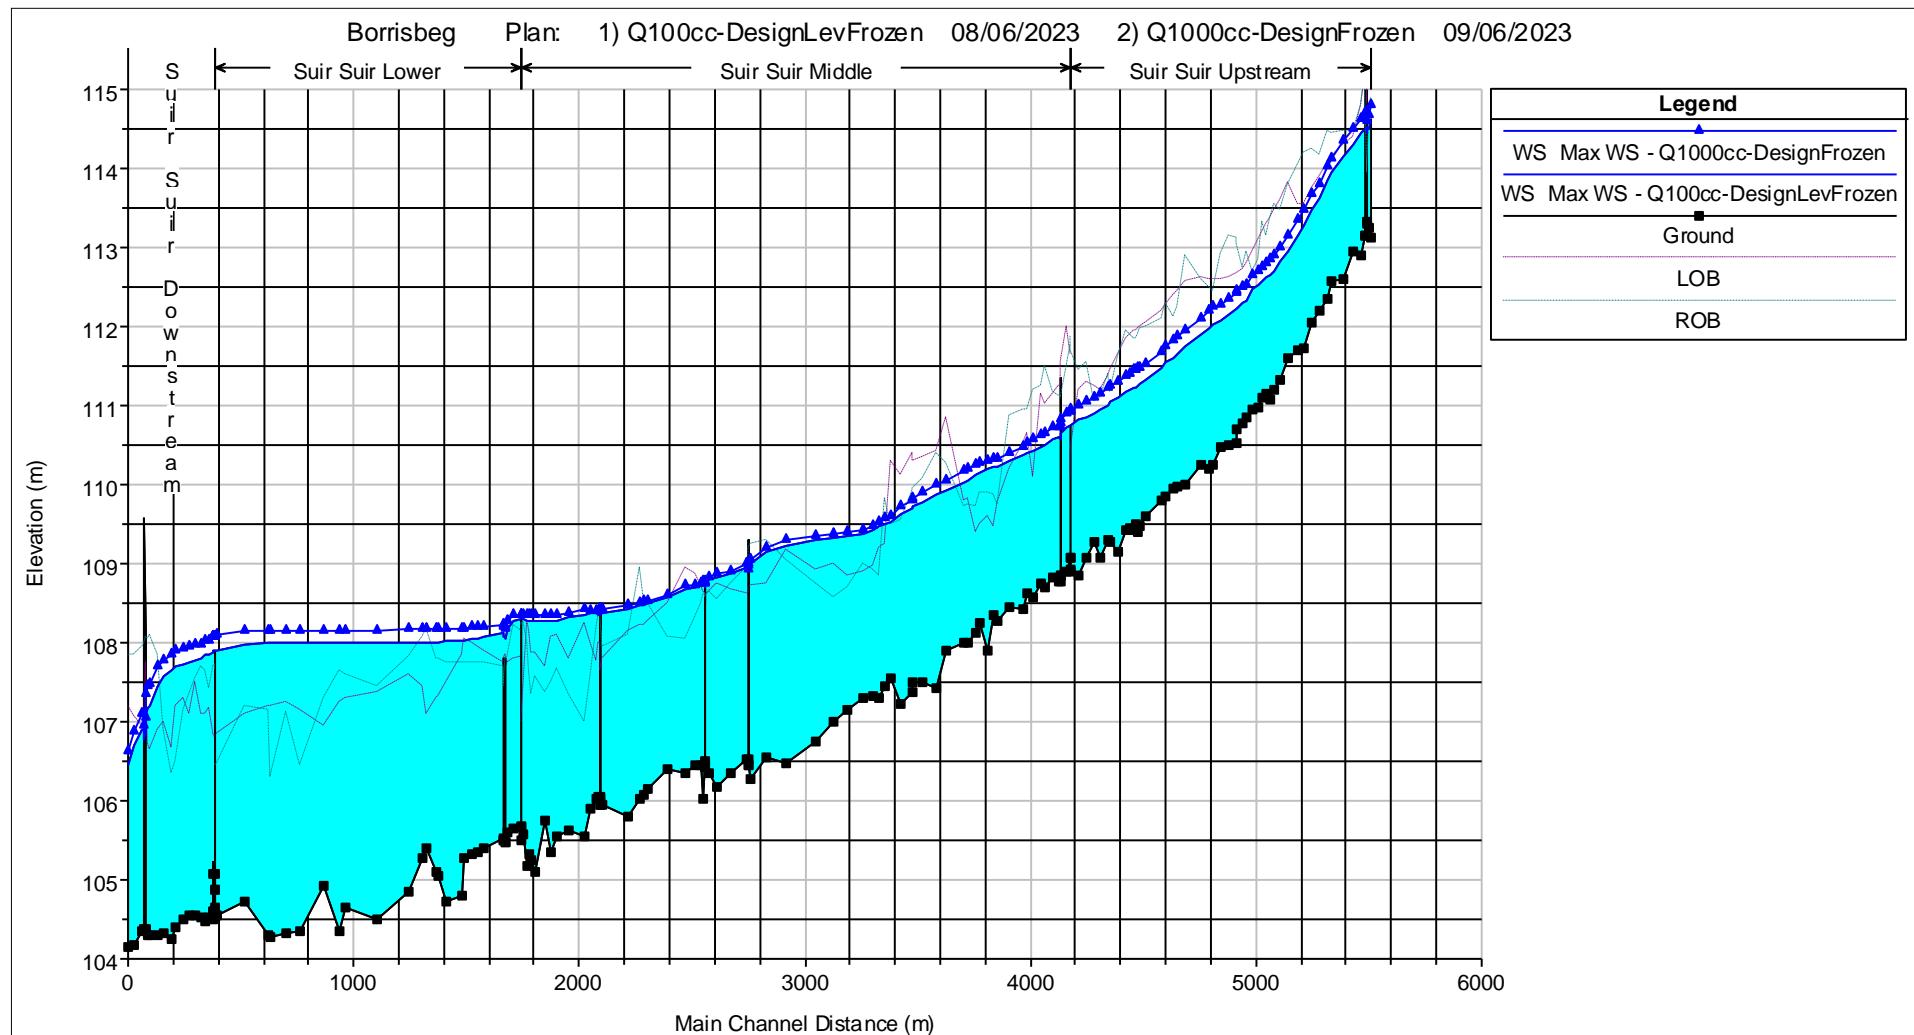

Figure 6.2. Suir Longitudinal profile showing water levels in the river channel for Design River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

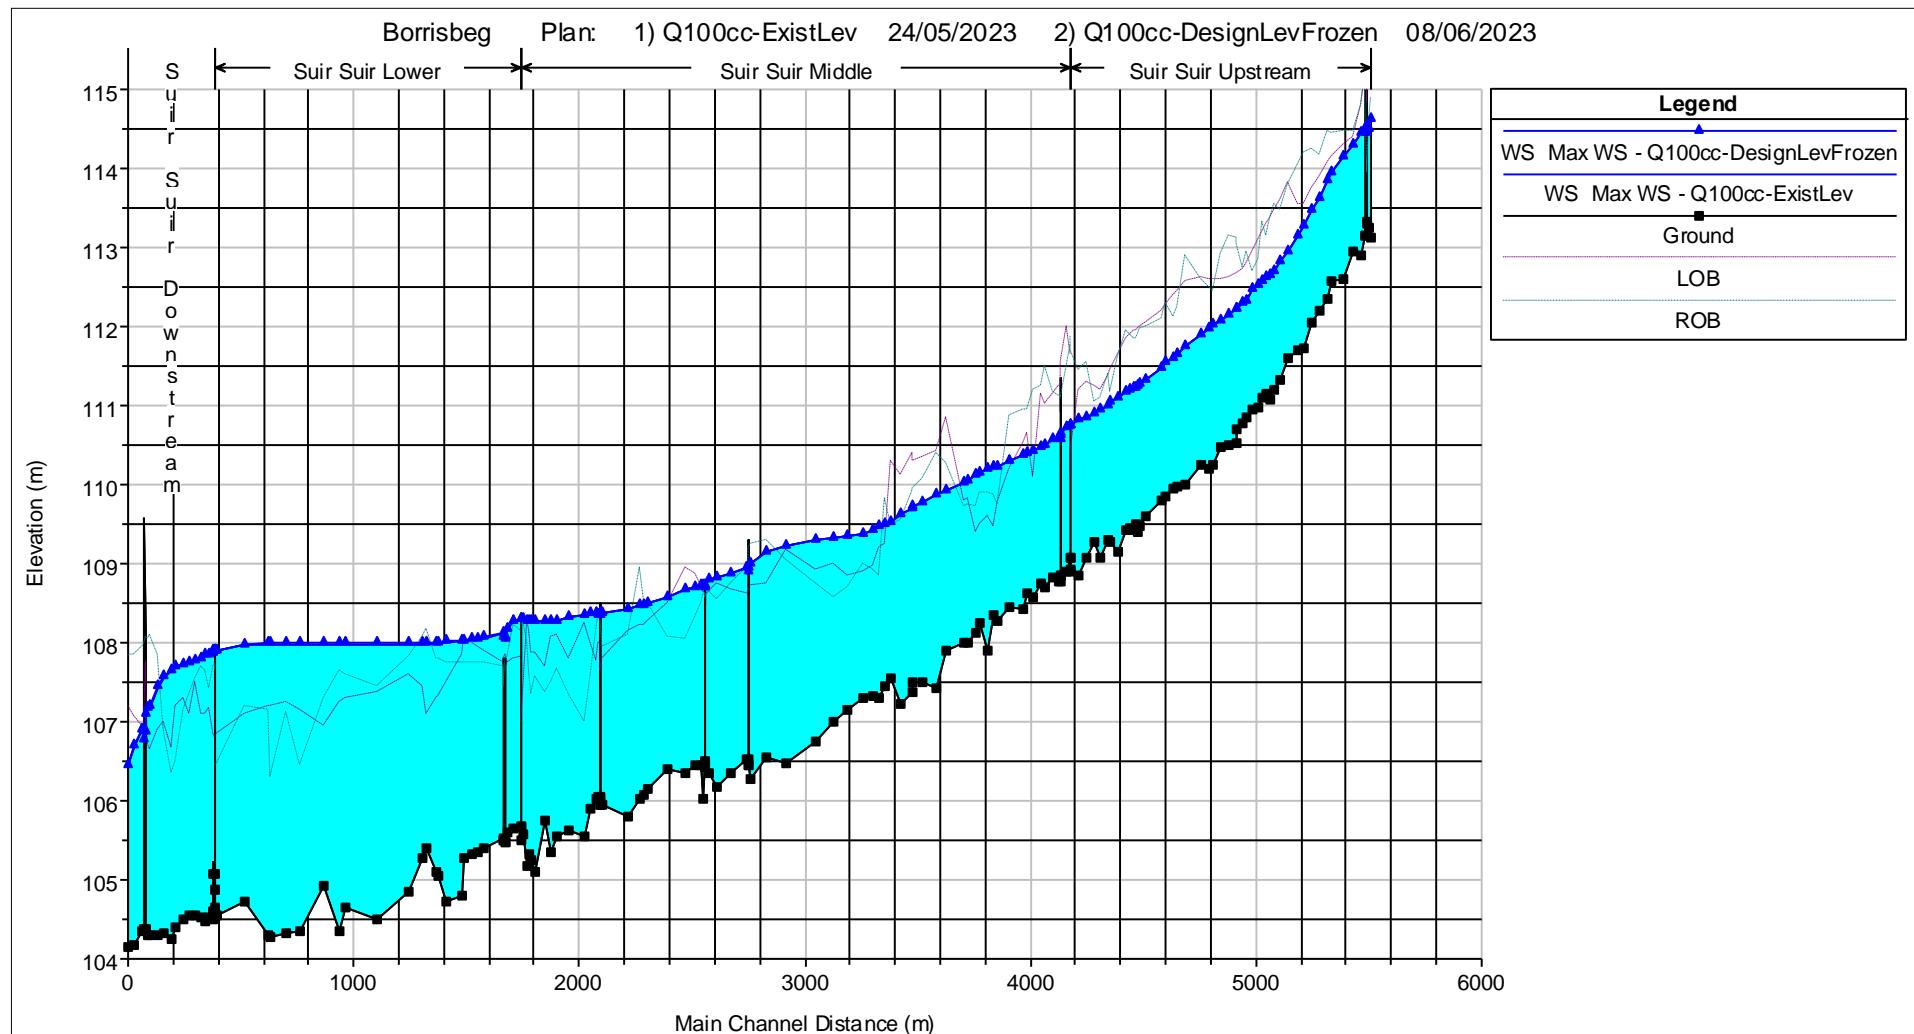

Figure 6.3. Suir Longitudinal profile comparing water levels in the river channel for Existing and Design River System for  $Q_{100cc}$ .

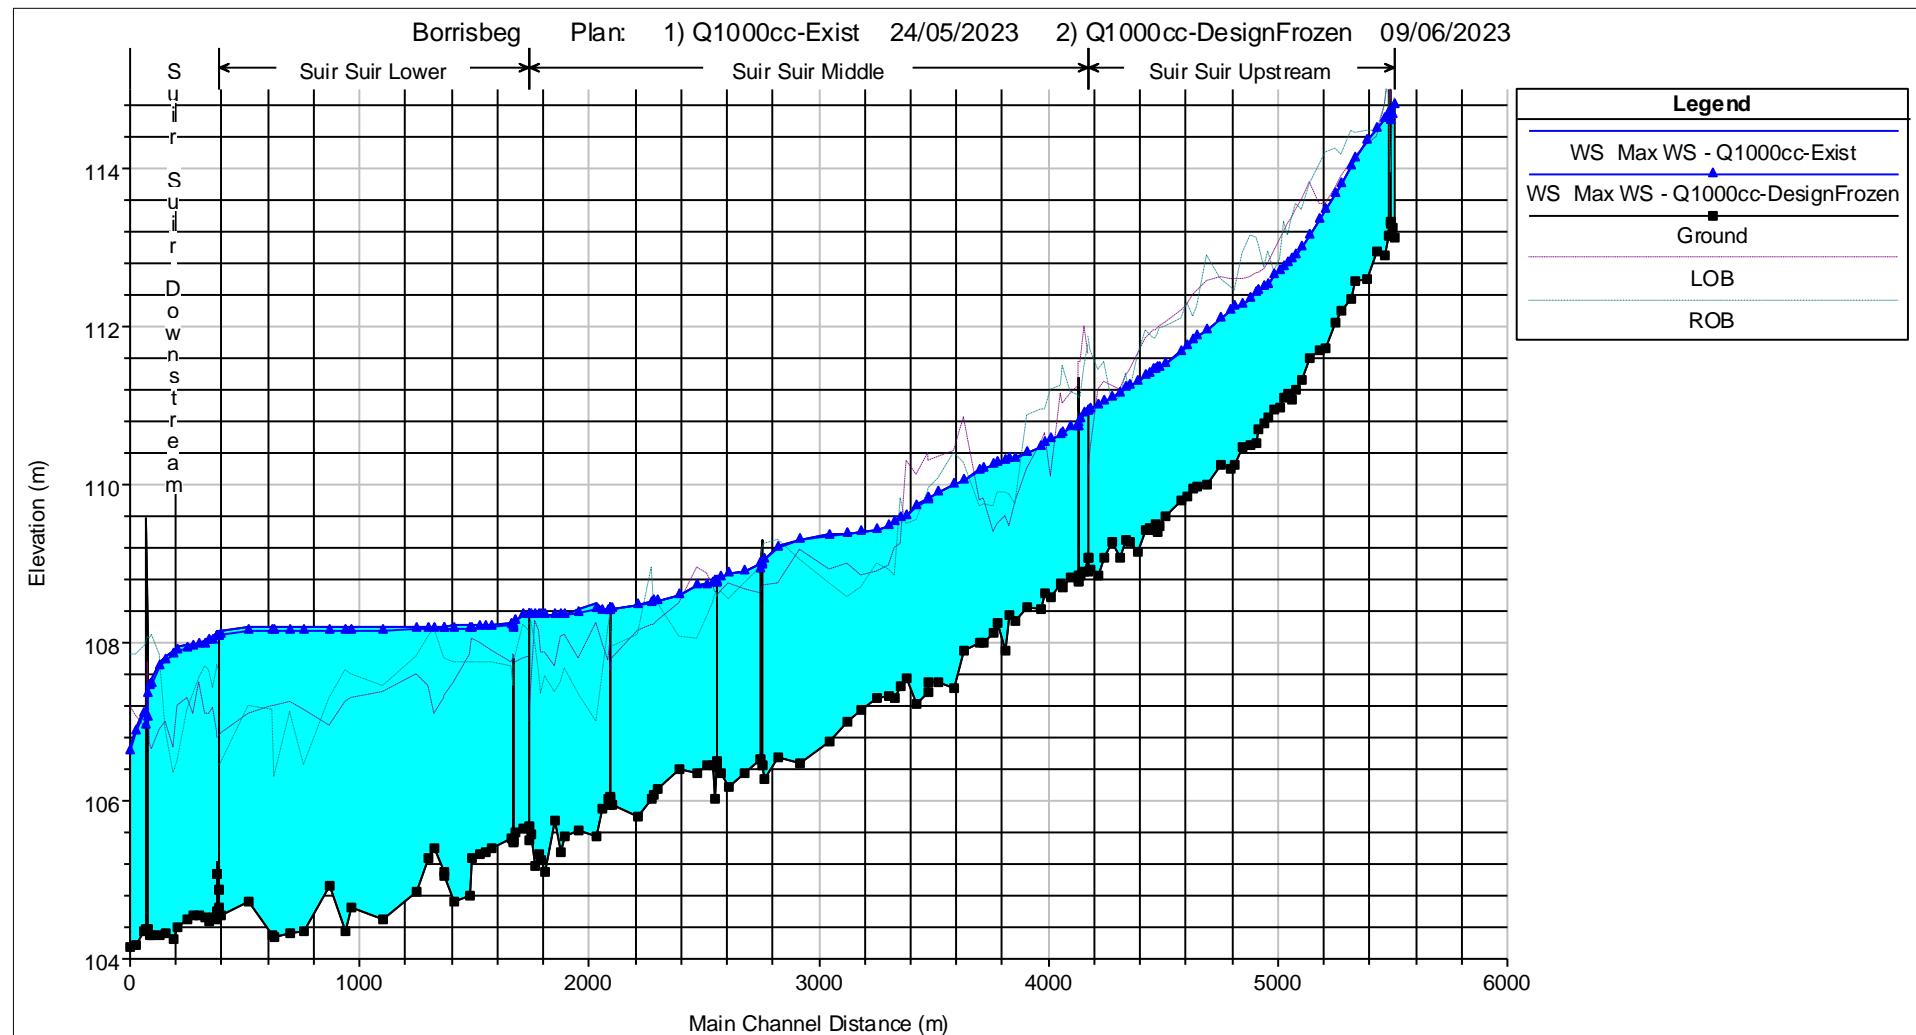

Figure 6.4. Suir Longitudinal profile comparing water levels in the river channel for Existing and Design River System for  $Q_{1000cc}$ .

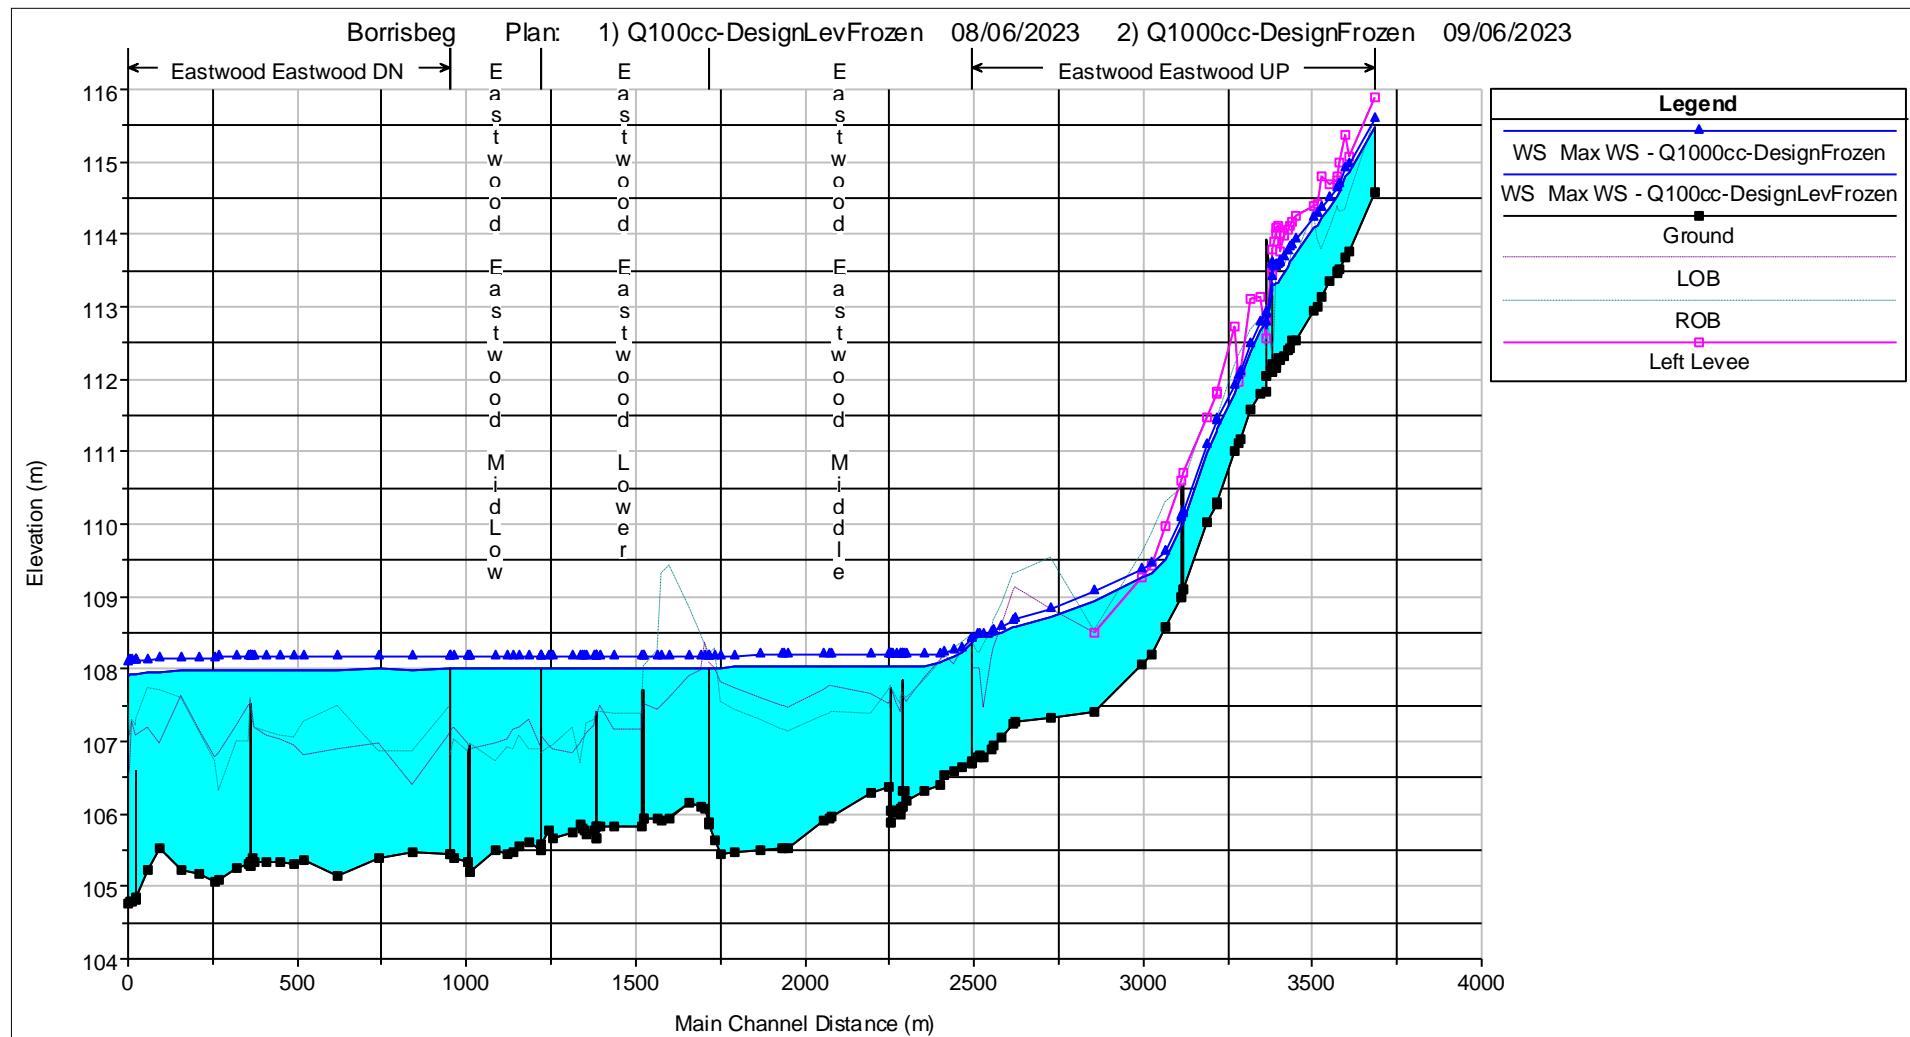

Figure 6.5. Eastwood Longitudinal profile showing water levels in the river channel for Design River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

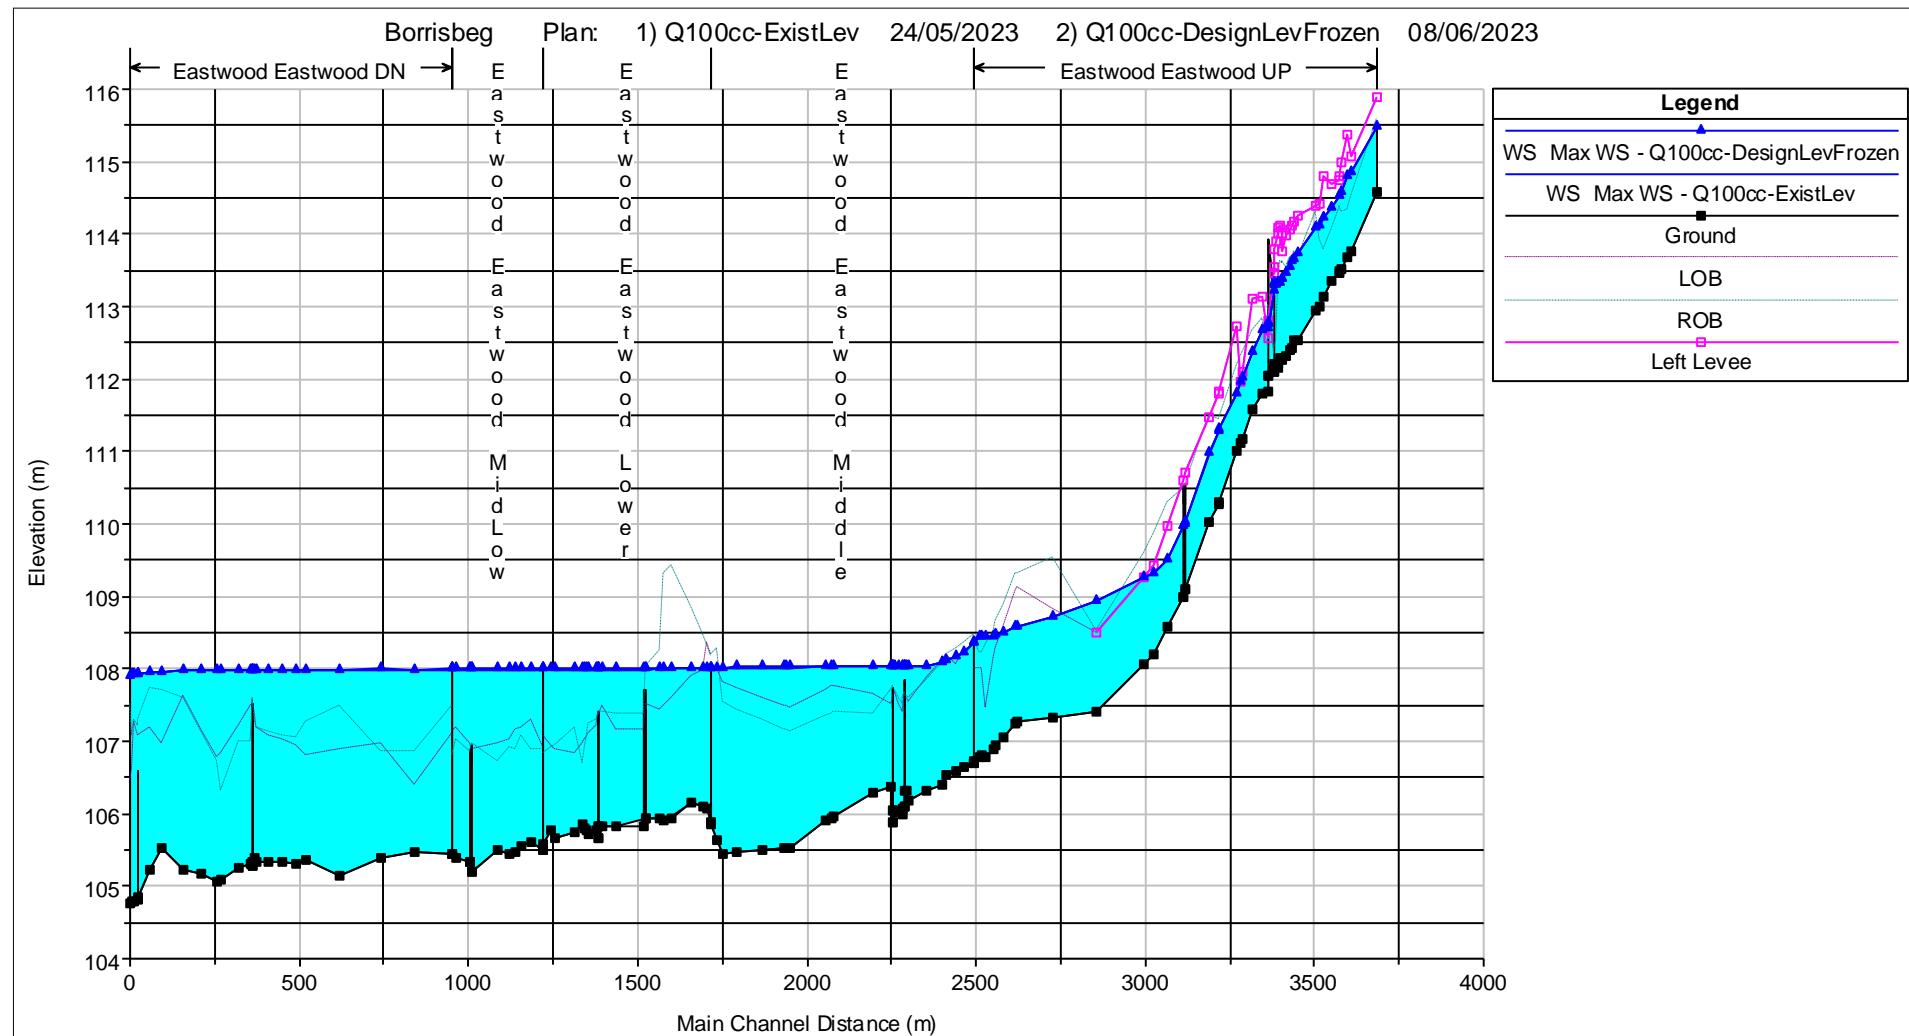

Figure 6.6. Eastwood Longitudinal profile comparing water levels in the river channel for Existing and Design River System for  $Q_{100cc}$ .

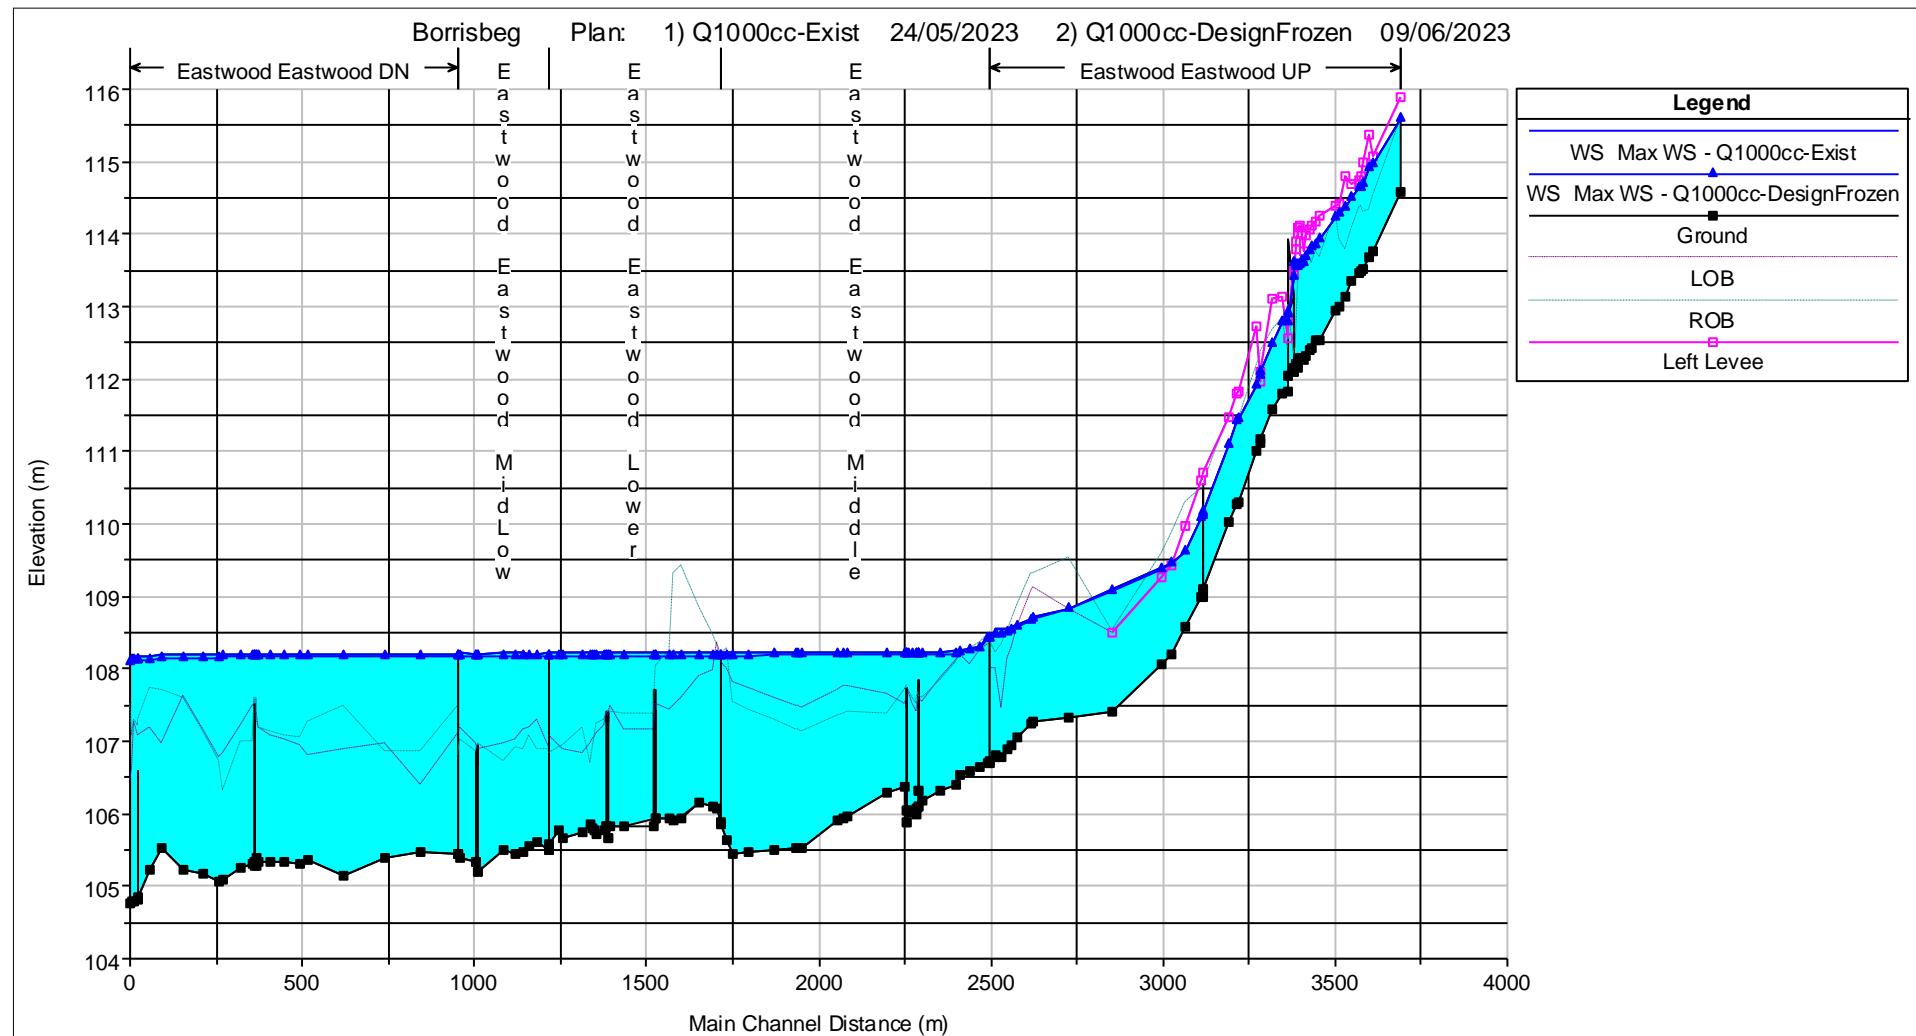

Figure 6.7. Eastwood Longitudinal profile comparing water levels in the river channel for Existing and Design River System for  $Q_{1000cc}$ .

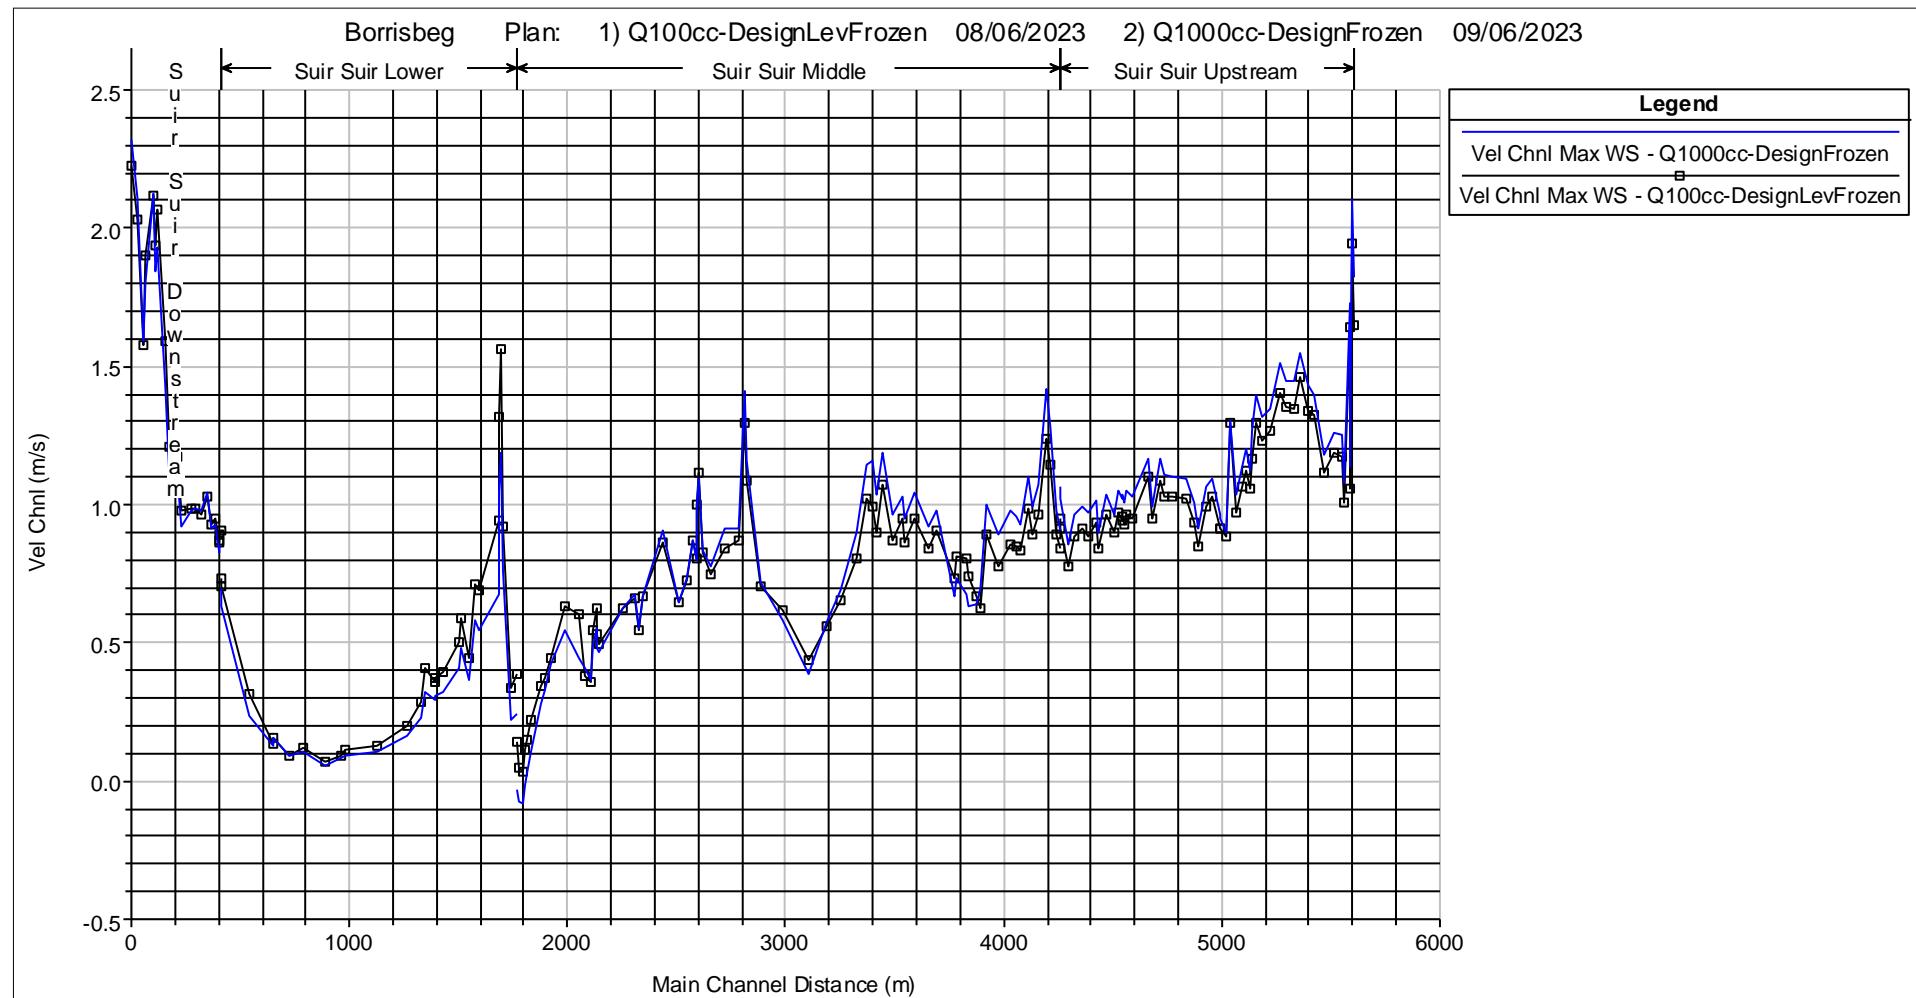

Figure 6.8. Suir Longitudinal profile showing flow velocity in the river channel for Existing and Design River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

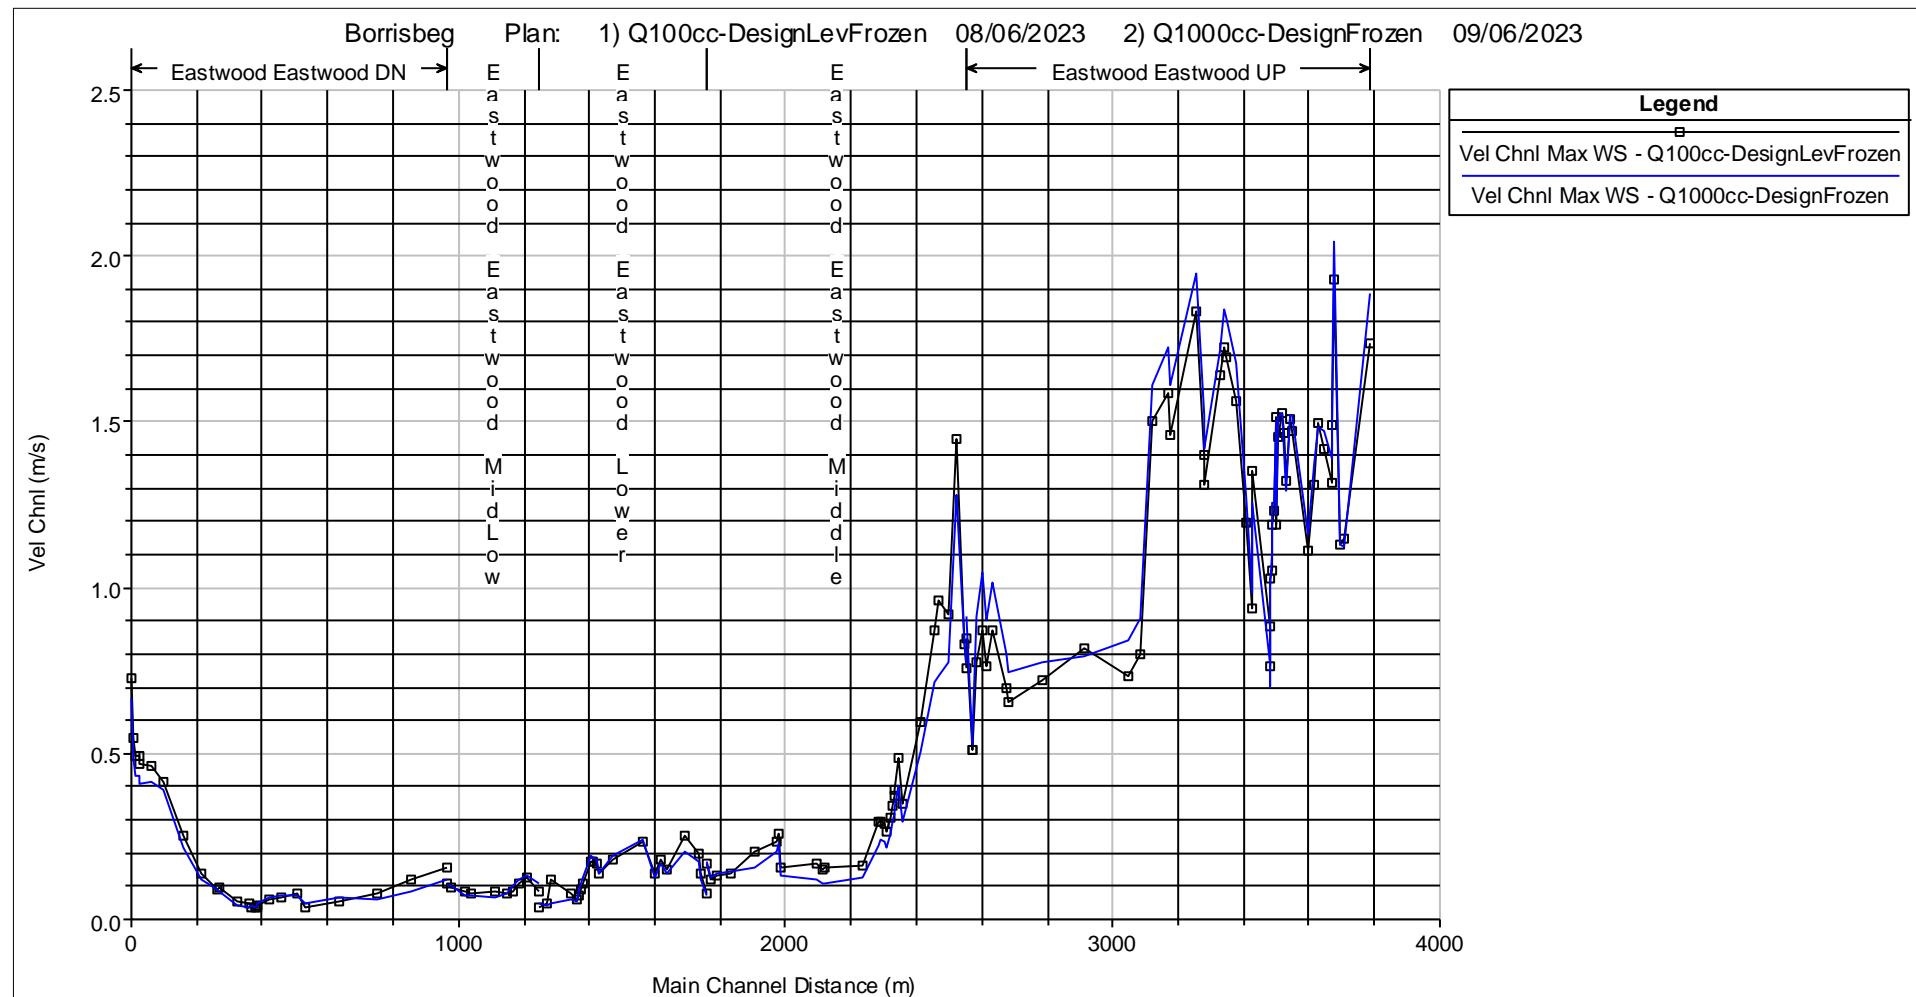

Figure 6.9. Eastwood Longitudinal profile showing flow velocity in the river channel for Design River System for  $Q_{100cc}$  and  $Q_{1000cc}$ .

## 6.2.5 Velocity distribution

A comparison of Figure 5.12 with Figure 6.8 data gives the impact on mean velocity along the River Suir a channel for the existing and design river systems. It is apparent that there is no perceptible change in the velocities. The velocities are relatively low and range between 1m/s and 2m/s along the river reach. These velocity values for such an extreme flood event should give no cause for concern for the development but as a precaution rock armouring of the hardstands, designed to withstand velocities in excess of 1.5m/s, should be provided at the appropriate locations.

A comparison of Figure 5.13 with Figure 6.9 gives the velocity distribution impact for the Eastwood channel and again the velocity pattern is similar; with velocities ranging from 0.5m/s to 2m/s.

**Note:**

*Figures which give velocity distributions and flood maps are in Appendices B & C and have the identifier label in the main text of Figure 8.1-Figure 8.2 and Figure 8.5-Figure 8.6.*

Figure 8.5 and Figure 8.6 (in Appendix B) give maps of the velocity distribution throughout the site for  $Q_{100cc}$  and  $Q_{1000cc}$ . It is clear that, in general, velocities are at an acceptable level and slightly higher velocities occur downstream of the wind farm.

## 6.2.6 Flood Maps for design System

Figure 8.7 (Appendix C) gives the flood map for the extreme 100-year flood with Climate Change factored in ( $Q_{100cc}$ ). The main access roads affected are in the vicinity of turbines T7, T8 and T9 where there is significant flooding with relatively high water depths (0.1 to 0.7m). It is important that the turbine hardstands at these locations should be elevated with ground levels higher than the extreme flood level. The access roads to these elevated hardstands should be ramped at a suitable gradient for heavy vehicle access. The Design model used in the hydrological/hydraulic simulations has accounted for elevated hardstands and ramped approach roads

Figure 8.8 (Appendix C) gives the flood map for the extreme 1000-year flood with Climate Change factored in ( $Q_{1000cc}$ ). The main access roads affected are in the vicinity of turbines T03, T04, T7, T8 and T9 where there is significant flooding with relatively high water depths (circa 0.4 to 1.4m). It is important that the turbine hardstands at these locations should be elevated constructions with ground levels c. 0.5m higher than the extreme flood level. The access roads to these elevated hardstands should be ramped at a suitable gradient. The Design model used in the hydrological/hydraulic simulations has accounted for elevated hardstands and ramped approach roads.

A comparison of the flood extent for Zone A and Zone B for Existing and Design river system is shown in Appendix C in Figure 8.9 and Figure 8.10 respectively. The impact of the wind turbine hardstands and roads on the flood extent for both flood zones A and B is minimal and is further discussed in section 6.4.3.

Figure 8.11 and Figure 8.12 in Appendix C show the difference between Design and Existing water levels for  $Q_{100cc}$  and  $Q_{1000cc}$  flood flows respectively. Only a minor water level rise of +0.01m is evident along the site for  $Q_{100cc}$  (Zone A) flows. This rise is associated with wind turbine hardstands which have been raised above extreme flood levels. For the  $Q_{1000cc}$  flows very little changes of water levels are noted when compared Design with Existing river system.

## 6.2.7 On site impact assessment

The proposed flood protection works for the development involve the construction of a flood terrace, to form the hardstands to a levels that are shown in Table 6.3 for turbines T03, T04, T07-T09.

A comparison of water levels and flow velocities in the channel, between existing and design river system imply that there would be no significant change in water levels and in flow velocities. **This means that all normal river flows remain unaffected by the proposed flood protection works.**

Some minor increase of flood extents (see section 6.4.3) due to the extraction of effective storage volume, (see 6.4.5) due to hardstands is noted, however this increase is localised and not significant.

An assessment of flow velocities for extreme flood flows shows that there will be no increase in the potential for erosion within main river channels. Furthermore, there will be no increase of flooding risk, since water levels are not increased by the development.

## 6.2.8 Flood Mitigation for design river system

### 6.2.8.1 Existing Culverts

The existing river system of main channels, tributaries and drainage channels has a number of existing culverts which influence the hydrological characteristics of the catchment. These culverts have been modelled accurately within the HEC-RAS model. The overall effect of these existing culverts is to increase the storage within the catchment thus attenuating flood flows. The development should not interfere with the existing storage and therefore the hydraulic characteristics of existing culverts should not be changed if possible.

### 6.2.8.2 New Culverts / Bridges

One new bridge (C1) and two new culverts (C1 and C3) will be required at points where the proposed access roads cross waterways. Figure 6.10 identifies the locations where new culverts are required. Proposed bridges and culverts with their location and description are listed in Table 6.2 below.

**Table 6.2. Proposed new bridges and culverts with description and location.**

No	Crossing ID	Type	X [m]	Y [m]	Shape: Dimensions (W, D, H, L)	Notes
1	C1	Culvert	613151.25	676139.94	Pipe: D =1.20m L = 5.5m	River Suir
2	C2	Bridge	612754.11	674311.31	Box: W=3m H=1.5m L = 6m	Eastwood
3	C3	Culvert	613300.03	674080.89	Pipe: D =0.90m L = 6.0m	Drain 01

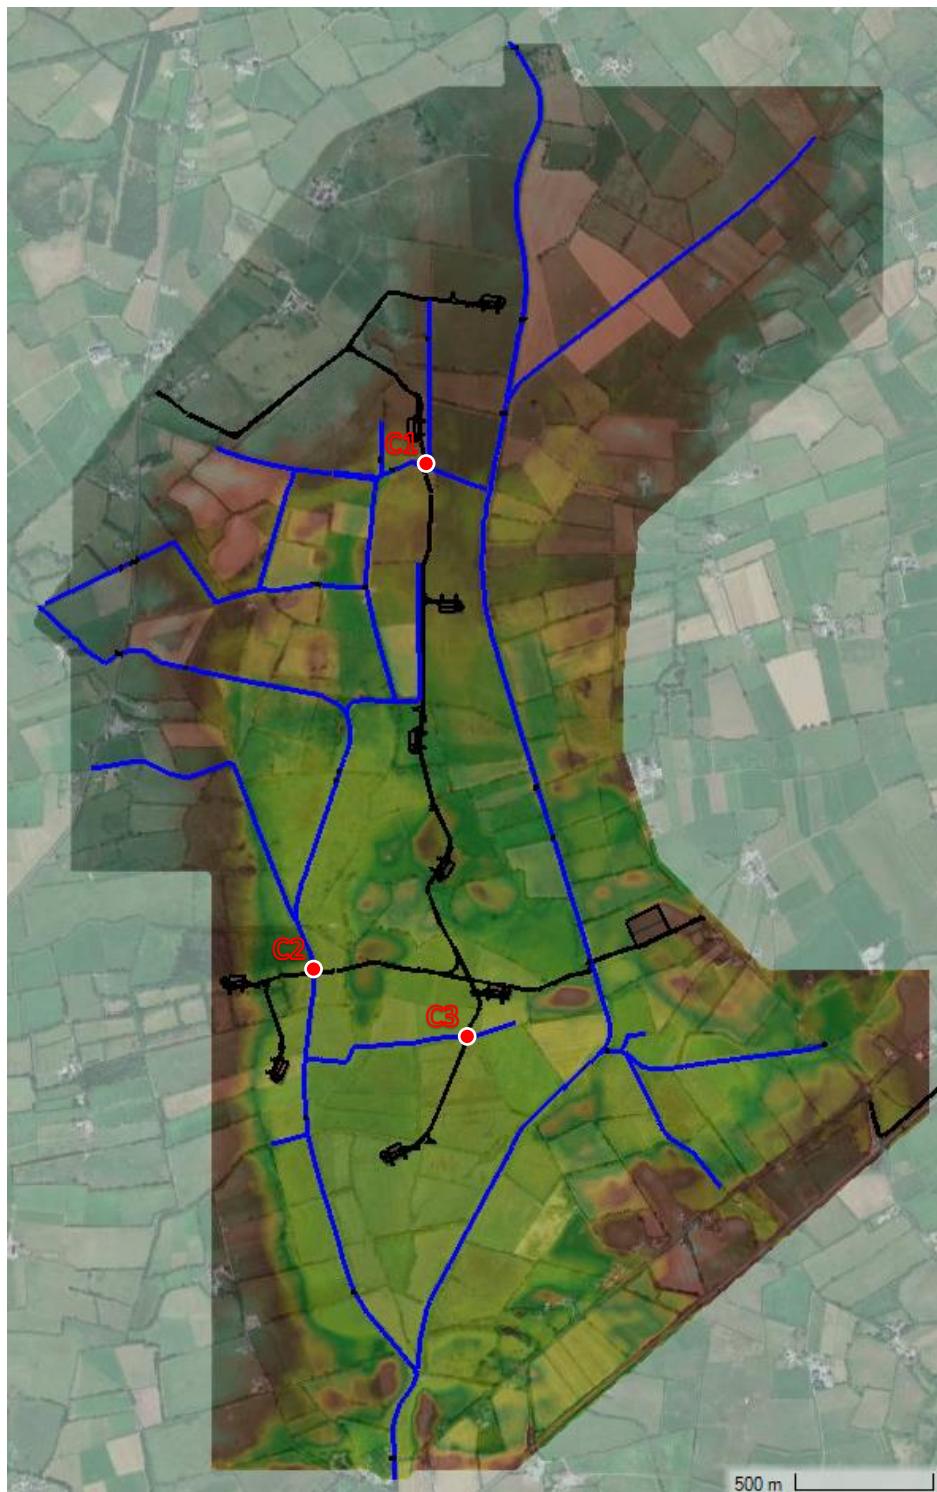

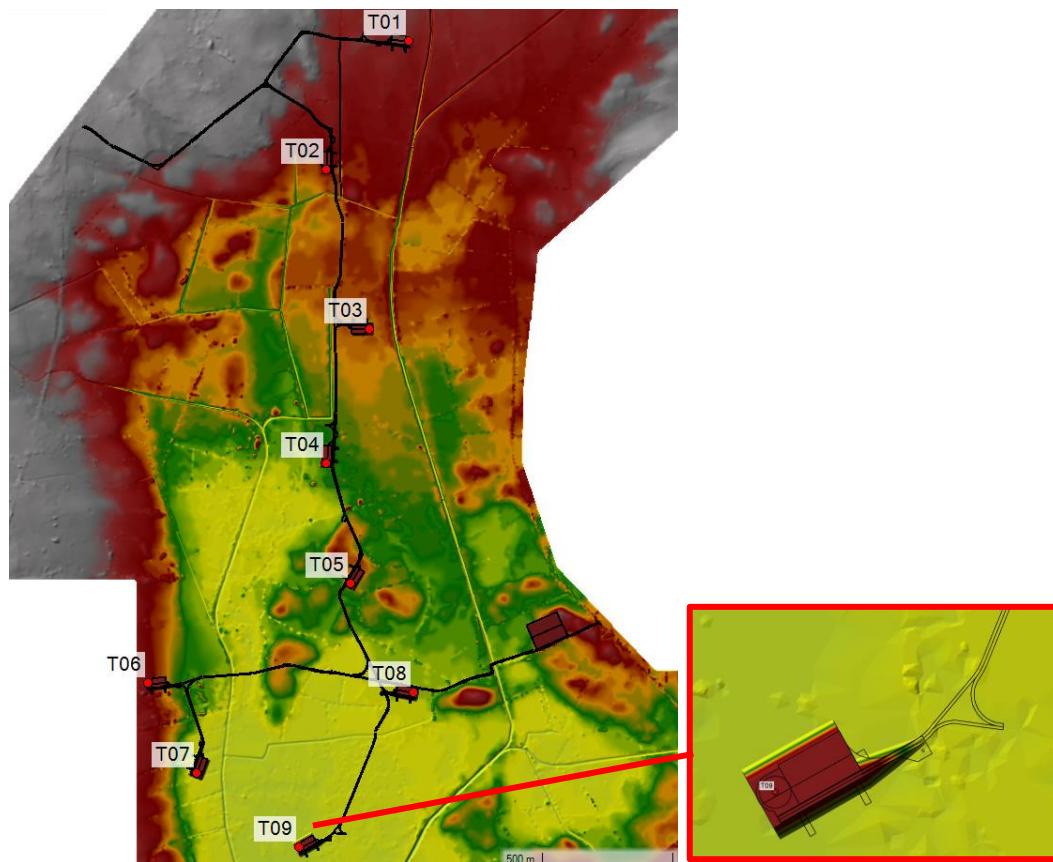

Figure 6.10. New culvert locations.

### 6.2.8.3 Wind turbine hardstands

Hardstands are required at each of the nine turbines and have been modelled in detail in the Design system HEC-RAS model. The hardstands required for turbines T03, T04, T07, T08 and T09 should have finished ground levels with freeboard of c. 0.5m above Q<sub>1000cc</sub> design flood levels, in accordance with table below.

**Table 6.3. Wind turbine hardstands Finished Ground levels.**

No	Turbine ID	Finished ground Levels FFL [mOD]	Q100cc		Q1000	
			WL [mOD]	Max Depth [m]	WL [mOD]	Max Depth [m]
1	T03	110.6	110.01	0.01	110.07	0.07
2	T04	109.3	108.76	0.05	108.82	0.10
3	T07	108.7	108.00	1.25	108.17	1.42
4	T08	108.7	108.13	0.52	108.21	0.60
5	T09	108.7	107.99	1.24	108.16	1.41

**Figure 6.11. Wind turbine Hardstands location and typical close-up layout.**

#### **6.2.8.4 Wind farm sub-station**

Windfarm sub-station is placed of Flood zones A and B.

### **6.3 ASSESSMENT OF SURFACE WATER DRAINAGE RISK**

#### **6.3.1 Calculations showing the pre- and post-development peak run-off flow rate for the critical rainfall event**

The OPW River Basin Management measures at the location of the site suggest to ‘ensure that all new developments incorporate sustainable drainage systems (SuDS)’ and ‘provide adequate storm water infrastructure in order to accommodate the planned levels of growth expected in the County’. The drainage from the site, e.g. from turbine hardstands and widened road network will be taken to the Suir and Eastwood rivers Notwithstanding the above, runoff calculations associated with the development are presented in this report for completeness.

The increased runoff from the site was calculated using the Modified Rational Formula. Based on an increase in impermeable surface area for ten turbine hardstands<sup>3</sup> (runoff coefficient = 0.9) from 0m<sup>2</sup> (existing - runoff coefficient = 0.5) to 61981m<sup>2</sup> (hardstands 3,143x9= 28,287m<sup>2</sup> and new proposed roads 33,694m<sup>2</sup>) the increase in runoff was determined for the 100-year rainstorm event. The rainfall intensity taken for this calculation was 106.2mm/hr obtained Met Eirann DDF tables (Annex I) for a duration of 10mins.

The calculation gave a total increase in flow to the river which peaks at a value of  $Q_{\text{increased}} = 0.73 \text{ m}^3/\text{s}$  ( $Q_{\text{design}} = 1.645 \text{ m}^3/\text{s} - Q_{\text{exist}} = 0.914 \text{ m}^3/\text{s}$ ). This is relatively low flow increase (1.8% of  $Q_{100cc}$  flow) and it is not expected to have effect on water levels in the river. Sustainable Drainage Systems is designed for the rain duration of 1hour for each turbine hardstand (Area of single hard stand is 3,143m<sup>2</sup>) and new design roads (33,694m<sup>2</sup>). The calculated volume of excess water in 1 hour per single hardstand is 334m<sup>3</sup> and for roads is 3358 m<sup>3</sup>. One option for SuDS:

- Design of open collection/attenuation ponds. The attenuation pond should be 1.0m deep with an area of 350m<sup>2</sup> per hardstand and 3600 m<sup>2</sup> for all roads. The attenuation ponds should be distributed at appropriate locations throughout the wind farm site taking advantage of natural depressions and existing drainage channels. (The attenuation ponds could tie in with silt management systems using silt traps which would normally be employed during construction).

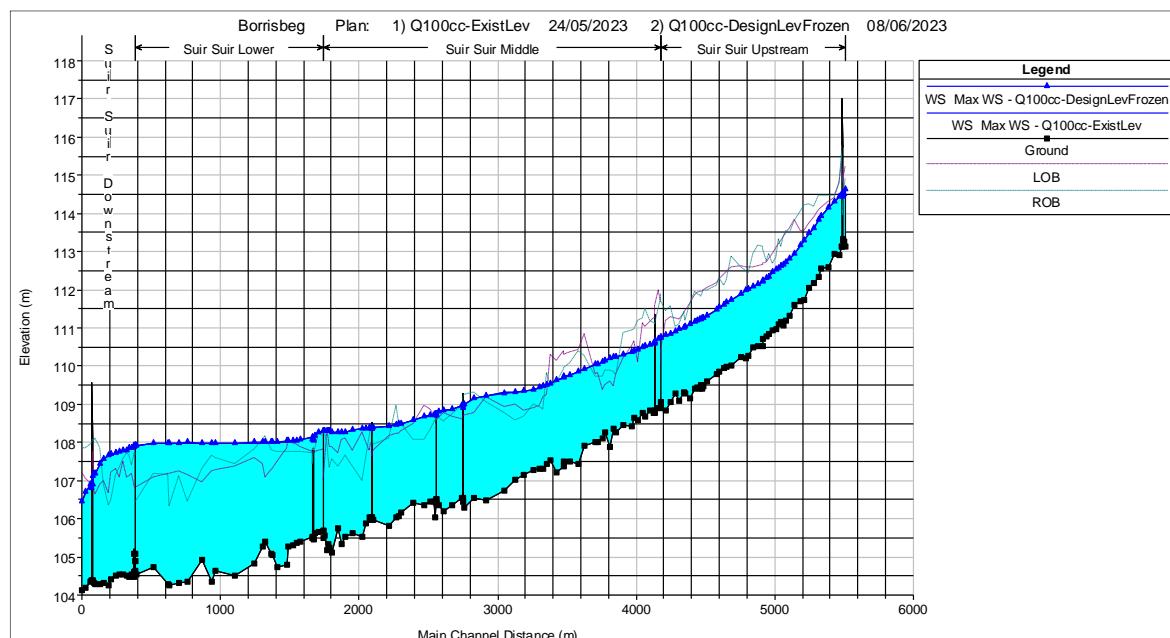

<sup>3</sup> Total area single turbine hardstand is 3143m<sup>2</sup>

## 6.4 POTENTIAL IMPACT OF DEVELOPMENT ON FLOODING ELSEWHERE

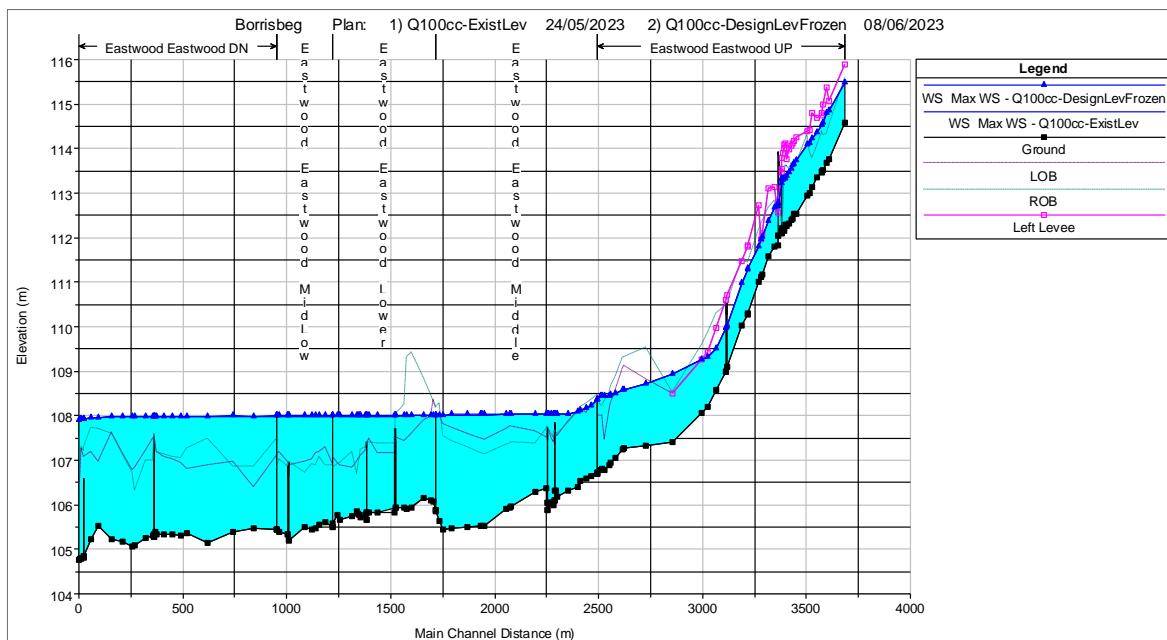

Proposals at the site must not worsen flood risk at other developments, be they upstream, downstream or adjacent to the site. The off-site impacts associated with the development are identified in sections below.

### 6.4.1 Water level comparisons

There are two main river channels within the zone of influence of the wind farm. The main River Suir channel and the Eastwood tributary channel. Figure 6.12 below, for the main River Suir channel, gives the longitudinal profiles for the Existing River System and the Final Design River System - one superimposed on the other. It is clear that the two water surface profiles are co-incident which confirms that the construction of the wind farm involving access roads and turbine hardstands has no impact on the water levels for the extreme Q<sub>100cc</sub> flood event. Figure 6.13 gives the Q<sub>100cc</sub> longitudinal profiles for the Eastwood channel and again the surface profiles are co-incident for the existing and Design River Systems confirming no water level change due to the windfarm construction.

**Figure 6.12. Suir Longitudinal profile showing water levels in the river channel for Existing and Design River System for Q<sub>100cc</sub>.**

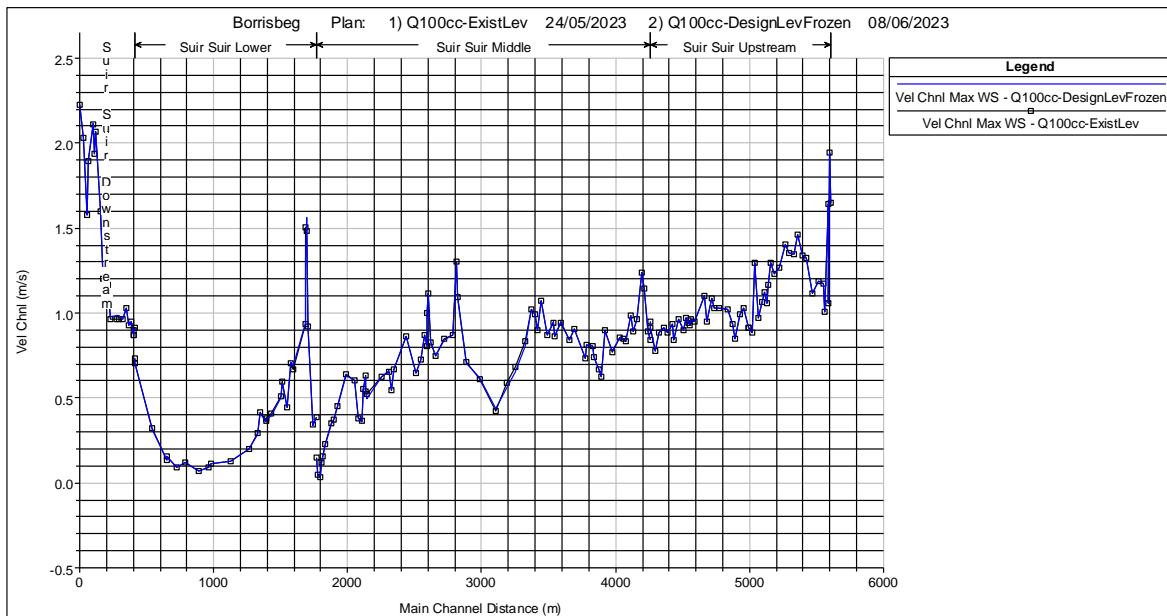

**Figure 6.13. Eastwood Longitudinal profile showing water levels in the river channel for Existing and Design River System for  $Q_{100cc}$ .**

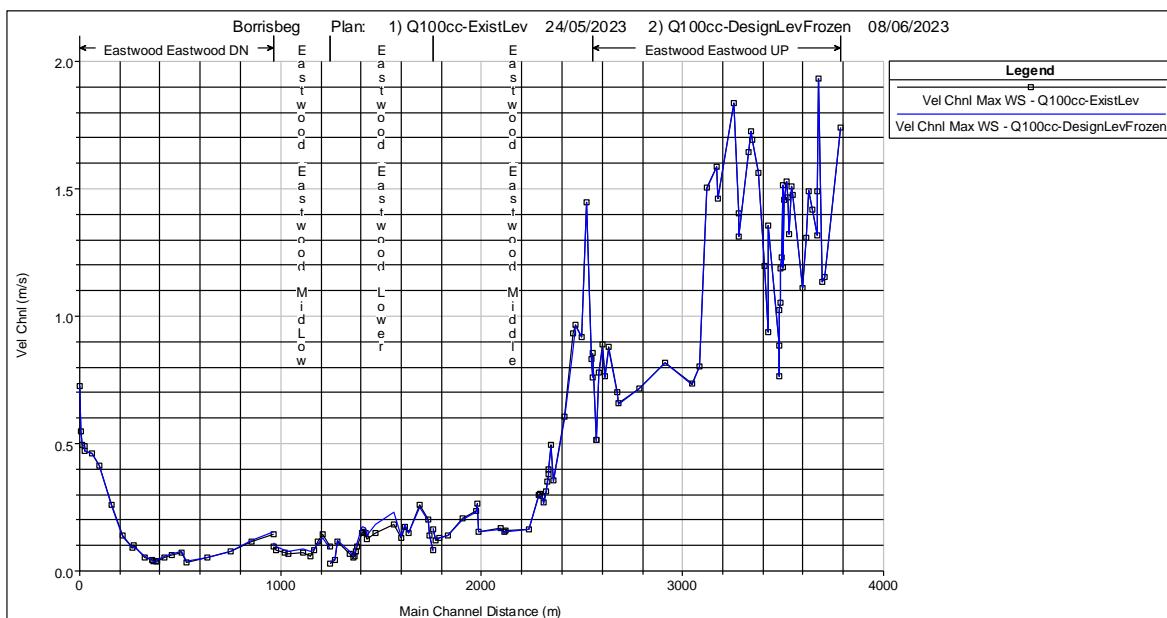

#### 6.4.2 $Q_{100cc}$ MRFS Velocity distributions

Figure 6.14 below gives the mean velocity along the River Suir channel for the existing and design river systems. It is apparent that there is no perceptible change in the velocities. The velocities range between 1m/s and 2m/s along the river reach. These velocity values for such an extreme flood event should give no cause for concern for the development but as a precaution, rock armouring of the hardstands, designed to withstand velocities of 2m/s should be provided at the appropriate locations.

Figure 6.15 gives the velocity distributions for the Eastwood channel and again the velocity pattern is similar; with velocities ranging from 0.5m/s to 2m/s.

**Figure 6.14. Suir Longitudinal profile showing flow velocity in the river channel for Existing and Design River System for  $Q_{100cc}$ .**

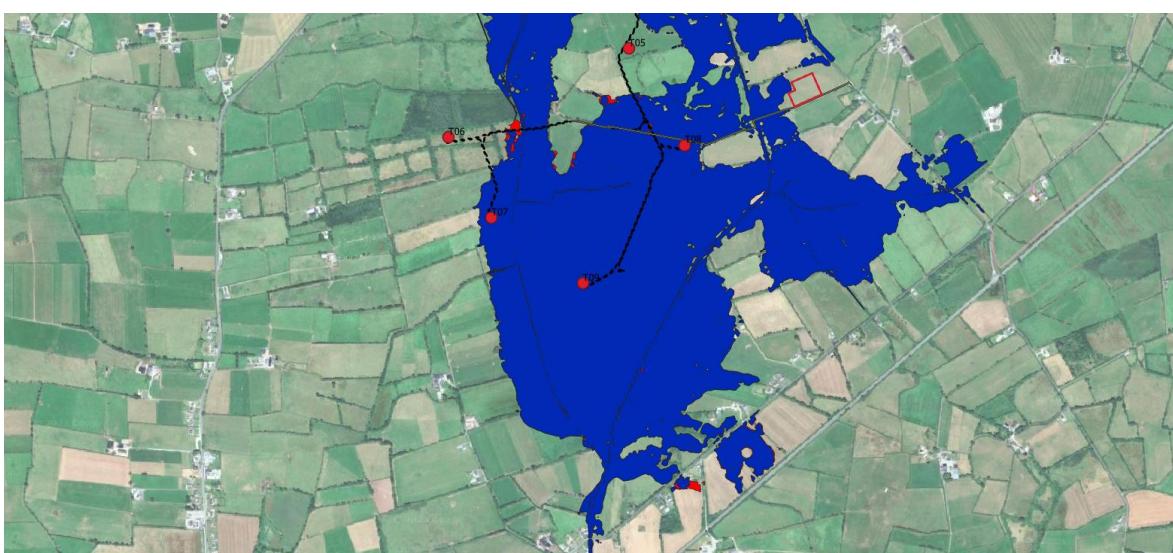

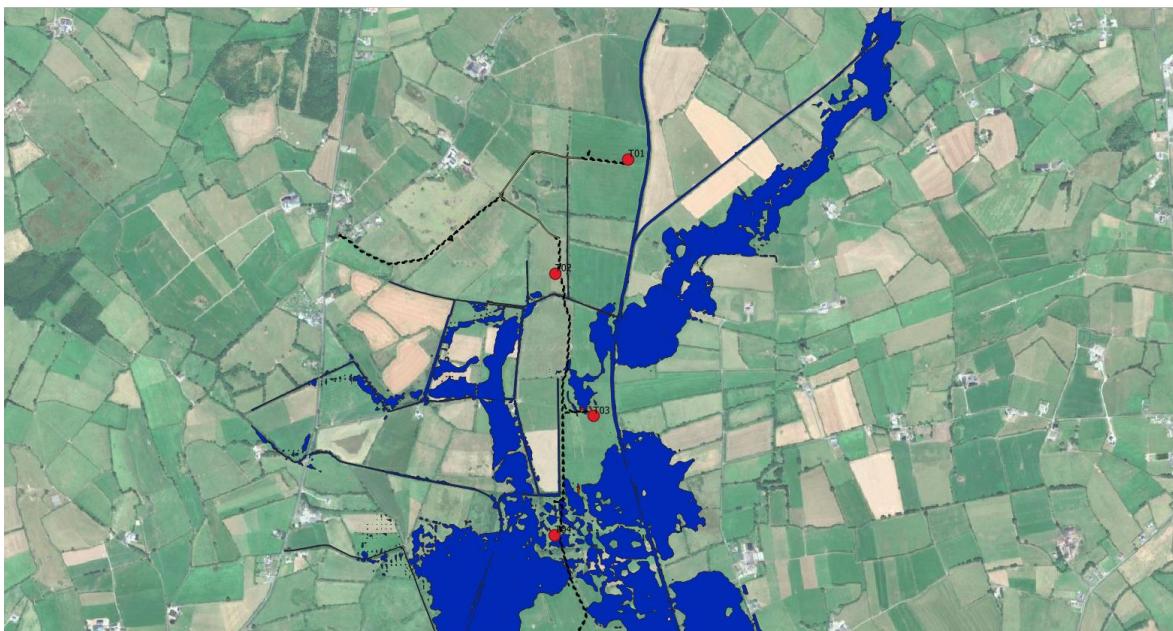

**Figure 6.15. Eastwood Longitudinal profile showing flow velocity in the river channel for Existing and Design River System for  $Q_{100cc}$ .**

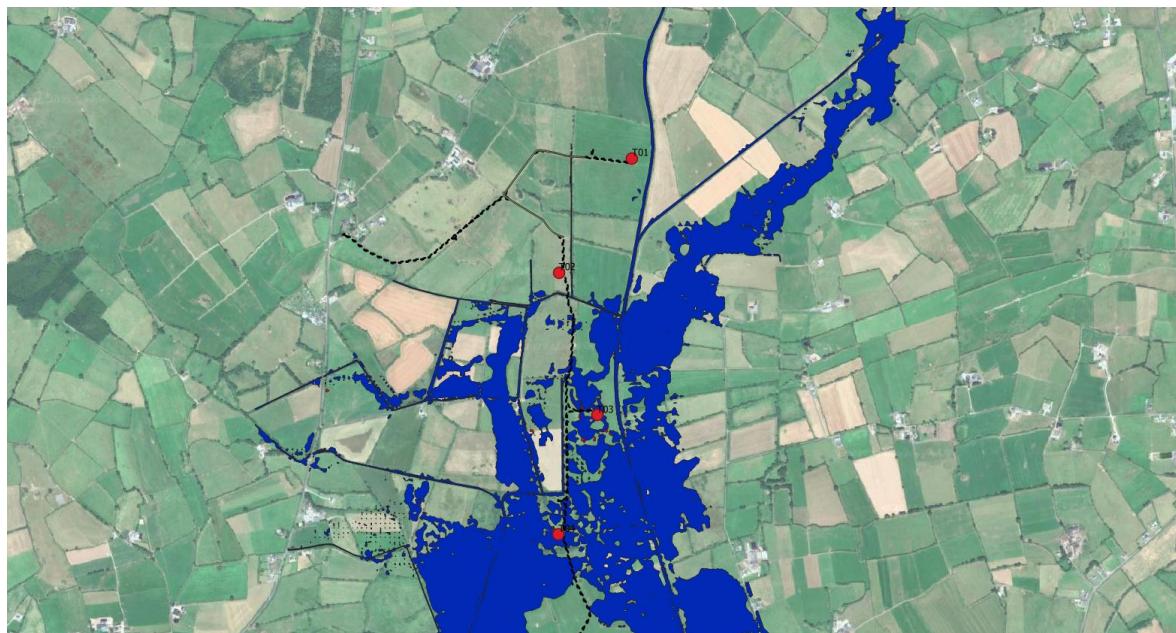

## 6.4.3 Flood Extent comparisons

Flood extent for both Zone A and B note small increase (almost imperceptible red hatch shown in figures below) of flood extent around the proposed site area (middle of the model) for the design river system. This increase in flood extent is associated with construction of turbine hardstands. Differences are more notable for flood Zone A –  $Q_{100cc}$ . than in flood Zone B –  $Q_{1000cc}$ .

### 6.4.3.1 Flood Zone A

#### 6.4.3.2 Flood Zone B

#### 6.4.4 Hydrograph comparisons for $Q_{100cc}$

The hydrographs for the existing river system was compared to the hydrograph for the design River system at a number of locations as shown in Figure 6.16 below.

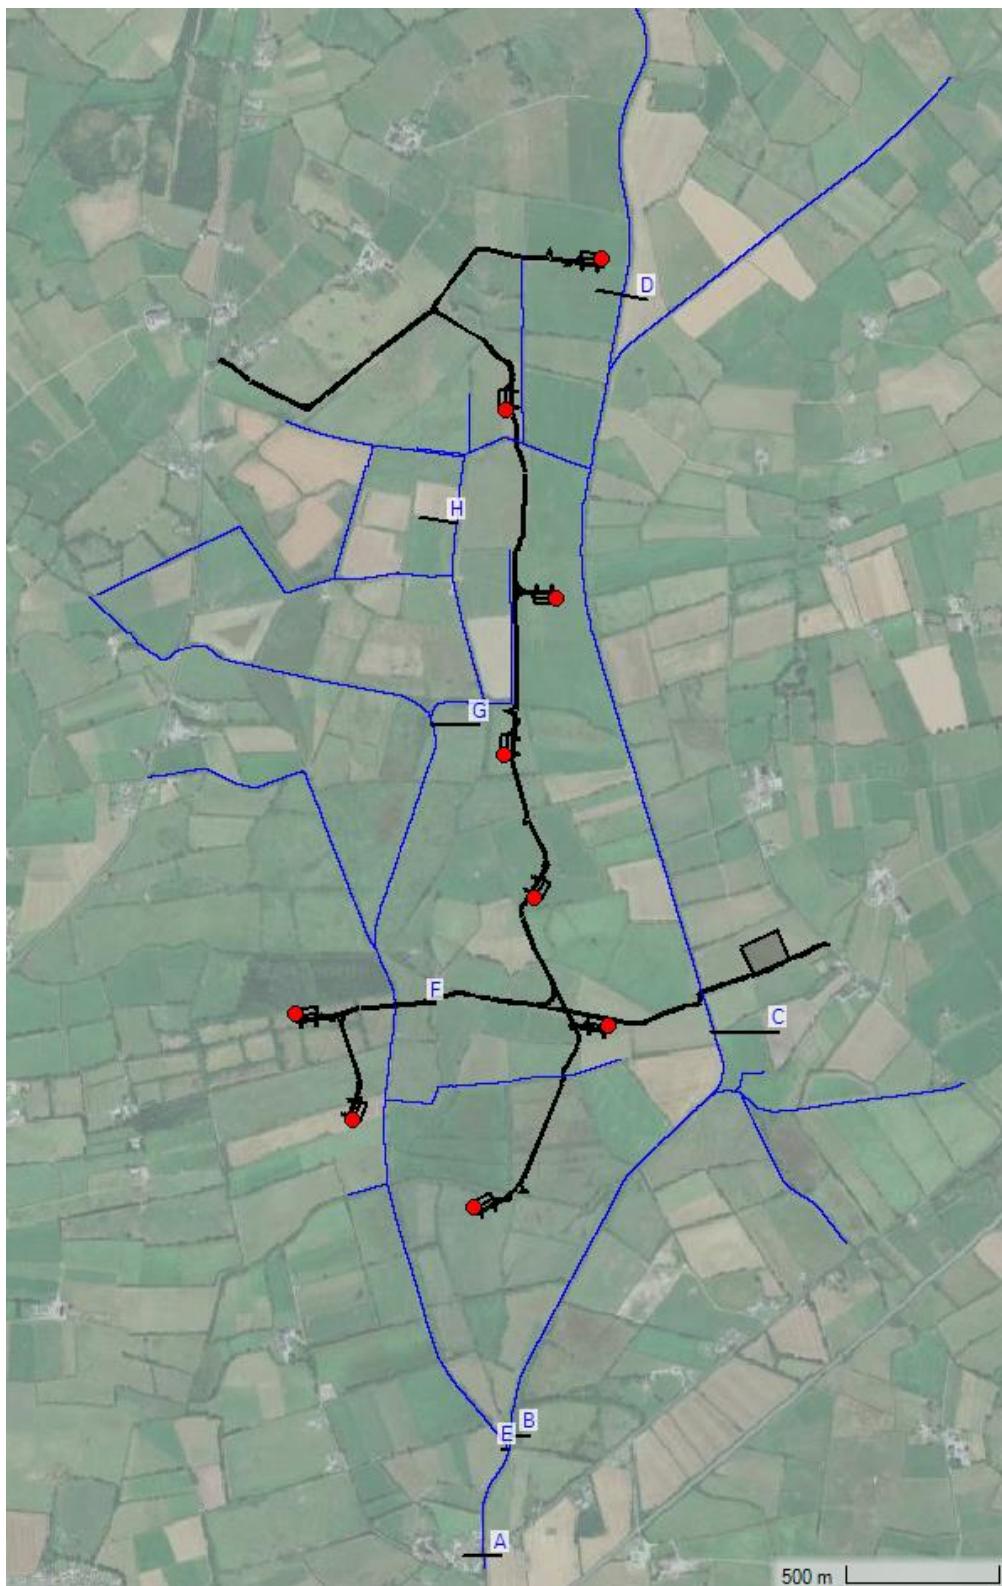

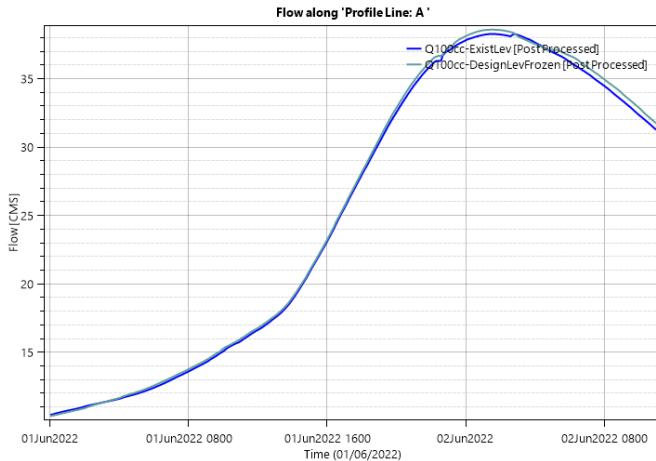

Figure 6.16. Hydrograph comparison locations for  $Q_{100cc}$  design flow.

Figure 6.17(a),(b),(c),(d),(e),(f) & (g) gives the comparisons and it is clear that there is only minor changes in the sub-catchment flood flow values at the downstream points (in some cases there is a flow reduction).

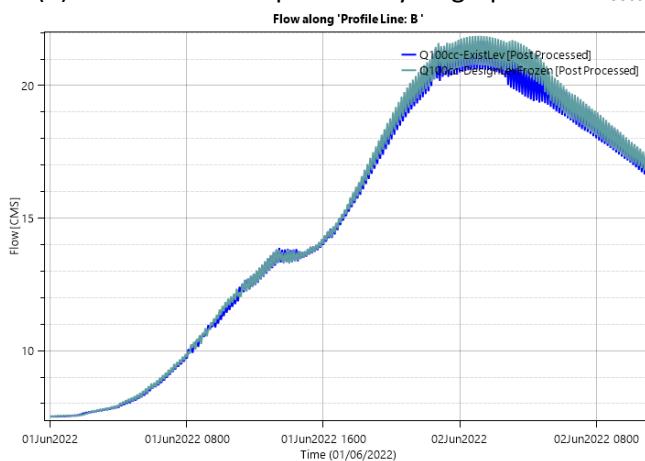

**Figure 6.17. Hydrograph comparisons at the above locations for  $Q_{100cc}$  design flow.**

(a) Location A - Output flow hydrographs for  $Q_{100cc}$

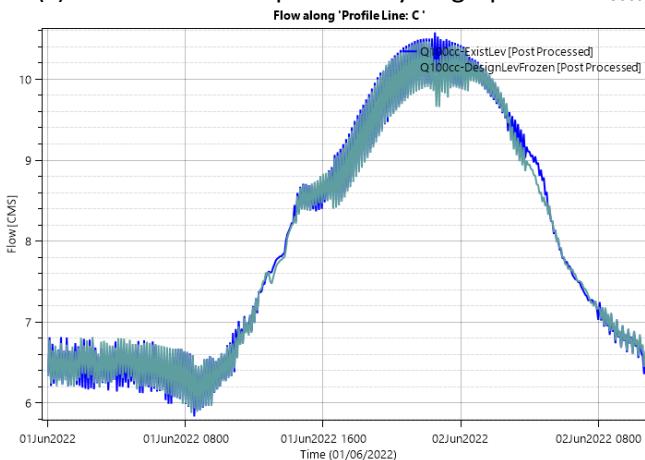

$Q_{100cc}$ Exist [m <sup>3</sup> /s]	$Q_{100cc}$ Design [m <sup>3</sup> /s]	$\Delta Q$ [m <sup>3</sup> /s]	$\Delta Q$ [%]
38.28	38.60	+0.32	+0.83%

(b) Location B - Output flow hydrographs for  $Q_{100cc}$

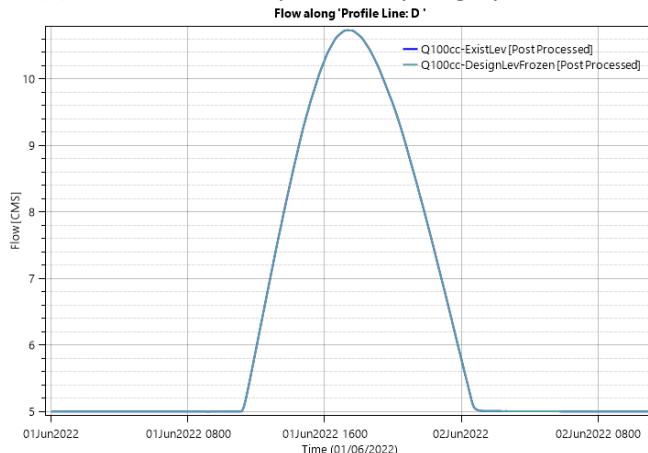

$Q_{100cc}$ Exist [m <sup>3</sup> /s]	$Q_{100cc}$ Design [m <sup>3</sup> /s]	$\Delta Q$ [m <sup>3</sup> /s]	$\Delta Q$ [%]
21.70	21.88	+0.18	+0.83%

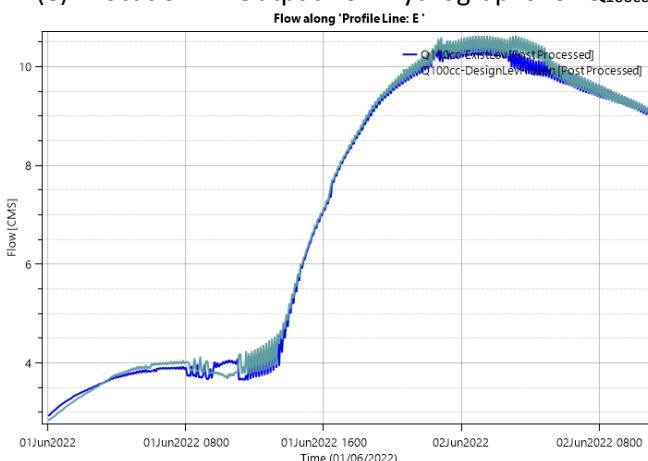

(c) Location C - Output flow hydrographs for  $Q_{100cc}$

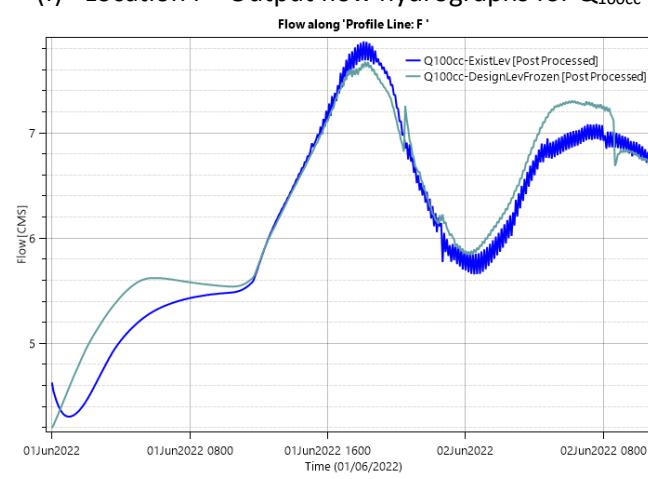

$Q_{100cc}$ Exist [m <sup>3</sup> /s]	$Q_{100cc}$ Design [m <sup>3</sup> /s]	$\Delta Q$ [m <sup>3</sup> /s]	$\Delta Q$ [%]
10.58	10.47	-0.11	-1.02%

(d) Location D - Output flow hydrographs for Q<sub>100cc</sub>

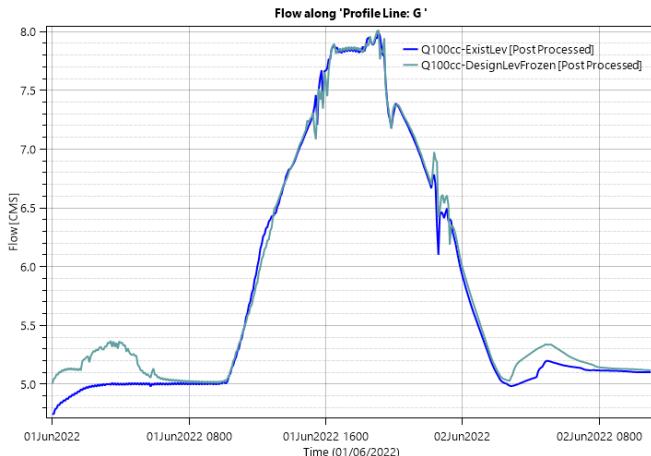

Q <sub>100cc</sub> Exist [m <sup>3</sup> /s]	Q <sub>100cc</sub> Design [m <sup>3</sup> /s]	ΔQ [m <sup>3</sup> /s]	ΔQ [%]
10.73	10.73	0.00	0.00%

(e) Location E - Output flow hydrographs for Q<sub>100cc</sub>

Q <sub>100cc</sub> Exist [m <sup>3</sup> /s]	Q <sub>100cc</sub> Design [m <sup>3</sup> /s]	ΔQ [m <sup>3</sup> /s]	ΔQ [%]
7.87	7.67	-0.19	-2.48%

(f) Location F - Output flow hydrographs for Q<sub>100cc</sub>

Q <sub>100cc</sub> Exist [m <sup>3</sup> /s]	Q <sub>100cc</sub> Design [m <sup>3</sup> /s]	ΔQ [m <sup>3</sup> /s]	ΔQ [%]
7.67	7.65	-0.01	-0.18%

(g) Location G - Output flow hydrographs for Q<sub>100cc</sub>

Q <sub>100cc</sub> Exist [m <sup>3</sup> /s]	Q <sub>100cc</sub> Design [m <sup>3</sup> /s]	ΔQ [m <sup>3</sup> /s]	ΔQ [%]
7.99	8.01	+0.02	+0.23%

#### 6.4.5 Loss of storage

Approximate loss of storage for Q<sub>1000cc</sub> flood event is around **storage loss of V<sub>loss</sub><sup>net</sup> = -8,014.65m<sup>3</sup> on the floodplain at the proposed site**. The figure V<sub>loss</sub><sup>net</sup> [m<sup>3</sup>] was calculated for a total of three hardstands with an area of 3143m<sup>2</sup> for each hardstand for turbines T07, T08 and T09 with average water depth of 0.75m, 0.40m and 1.40m respectively (conservative approximation).

#### 6.4.6 Increased run-off

The increase of run-off due to construction of hardstands is mitigated by incorporating a SuDS system of runoff management. The potential increase of the runoff due to construction of hardstands is estimated to be 0.73m<sup>3</sup>/s (see section 6.3.1). SuDS are therefore required. The runoff increase and proposed SuDS dimensions are given in section 6.3.1.

## 6.5 RESIDUAL RISKS

Residual flood risks include the failure of flood management infrastructure or a severe flood event that exceeds a flood design standard.

### 6.5.1 Failure scenarios and flood resilient building design

According to the OPW Guidance, assessment of flood defence breaching should be undertaken on the basis of a design event of the appropriate design standard. The flood protection system involving a raised terrace which is extremely stable, is not liable to structural failure in the same way as an embankment or levee and as such does not pose a risk due to failure.

The proposed design standard is 1% AEP for river flooding and 0.5% AEP for flooding from the sea, including an allowance for climate change. Assessment of overtopping of flood defences should be undertaken on the basis of the 0.1% AEP event, including an allowance for climate change.

In order to mitigate residual flood risk, it is proposed that the properties should be constructed with their finished floor/ground levels at such a height greater than:

(the 1000-year flood) + (an allowance for climate change) + freeboard

There is a single pronounced levee Figure 3.3 at the left bank of Eastwood Stream. The residual risk of this levee was tested by modelling of the system with and without (failure) of this levee. The analysis showed no difference in flood extent or water levels as the levee is overtopped and flooded for both  $Q_{100cc}$  and  $Q_{1000cc}$  flood flows. Therefore there is no risk associated with failure scenarios.

### 6.5.2 Access and egress

According to the flood extent maps and Figure 6.18, access and egress to and from the site is provided at two points first is on the west at N62 road and second to the East from local road L7039.

Both access and egress points are not prone to flooding.

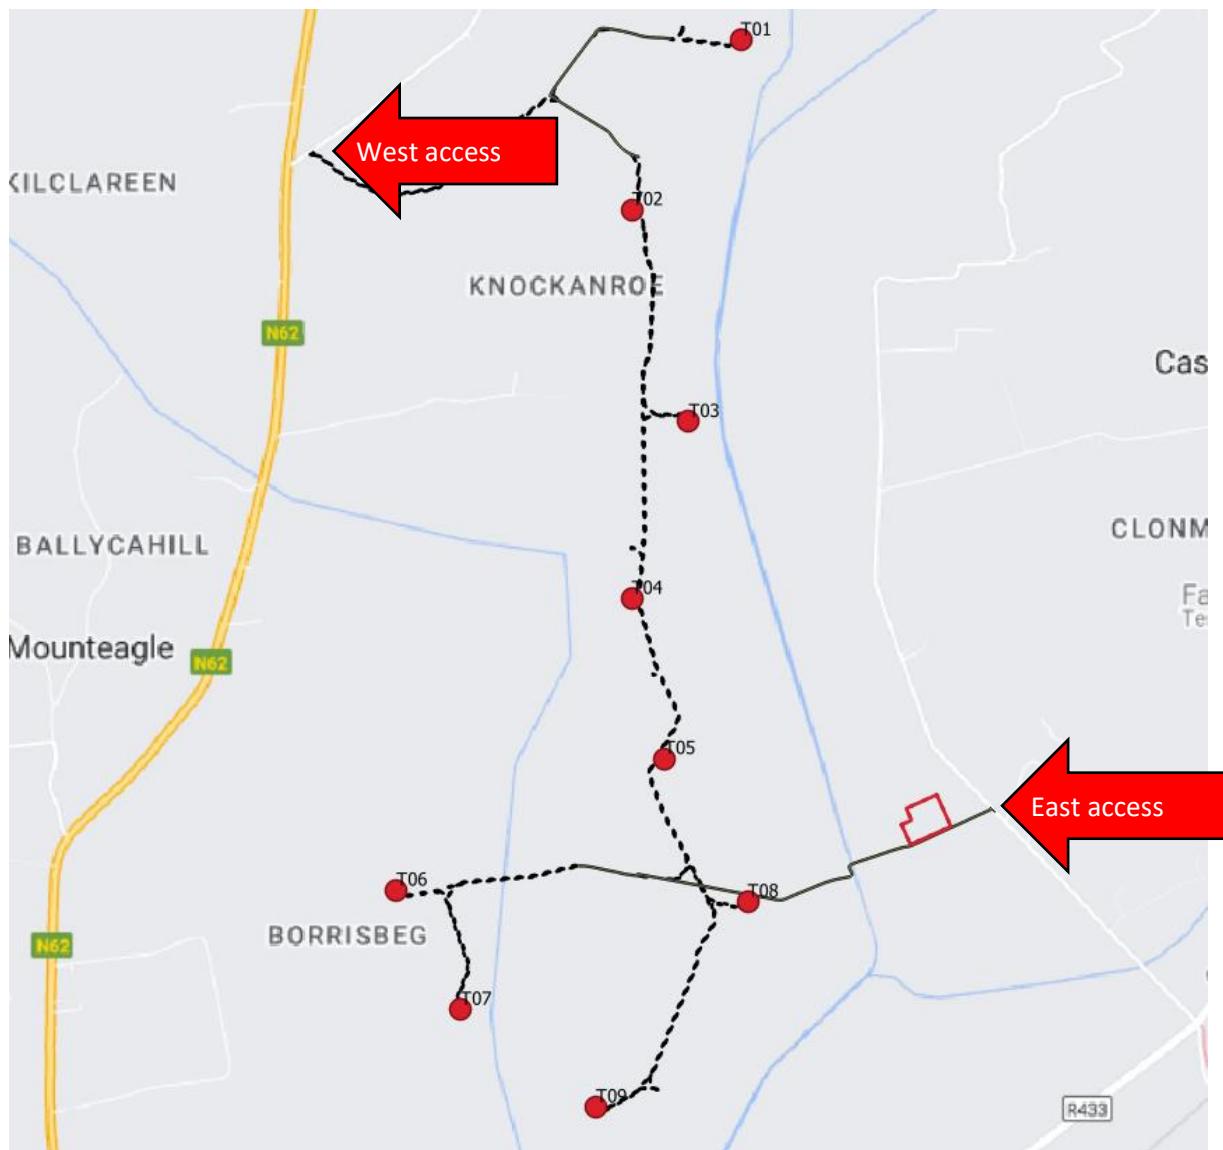

Figure 6.18. Layout of emergency access and egress road

## 6.6 JUSTIFICATION TEST

The Justification Test of the OPW Guidelines [1] has been designed to rigorously assess the appropriateness, or otherwise, of particular developments that are being considered in areas of moderate or high flood risk.

According to the requirements of the Guidelines, in the Justification Test, a sequentially-based decision-making process was applied, through Part 1 and Part 2 presented below.

The first is the Plan-making Justification Test described in chapter 4 of the Guidelines [1] and used at the plan preparation and adoption stage where it is intended to zone or otherwise designate land which is at moderate or high risk of flooding. The second part relates to the development management.

### 6.6.1 Part 1 - Plan Making Justification Test

As the proposed development site falls within Zone A with high risk of flooding, a Justification Test needs to be undertaken to review issues of proper planning and sustainable development.

The proposed development site is located north of town Templemore in Co. Tipperary, and is at risk of fluvial flooding (Flood zone A). The site is outside of Local Area Plans as shown in Annex D. However, according to the Co. Tipperary Energy plan as part of Development Plan 2022-2028 [11] (Figure 0.1 and Figure 0.2) the site is within “Areas Open for Consideration for New Wind Energy Development”.

Therefore it can be concluded that the requirements of Justification Test Part 1 are **satisfied**.

### 6.6.2 Part 2 – Development Management Justification Test

If the requirements of Part 1 are satisfied, then the following additional detailed criterion should also be met. The development has been the subject of a sufficiently detailed Flood Risk Assessment, as appropriate to the nature and scale of the development, and the potential risk that may arise, which is demonstrated below.

This abstract from the OPW Guidelines [1] describe the Justification Test application.

“

#### Application of the Justification Test in development management

- 5.15 Where a planning authority is considering proposals for new development in areas at a high or moderate risk of flooding that include types of development that are vulnerable to flooding and that would generally be inappropriate as set out in Table 3.2, the planning authority must be satisfied that the development satisfies all of the criteria of the Justification Test as it applies to development management outlined in Box 5.1 below.

**Box 5.1 Justification Test for development management  
(to be submitted by the applicant)**

When considering proposals for development, which may be vulnerable to flooding, and that would generally be inappropriate as set out in Table 3.2, the following criteria must be satisfied:

1. The subject lands have been zoned or otherwise designated for the particular use or form of development in an operative development plan, which has been adopted or varied taking account of these Guidelines.
2. The proposal has been subject to an appropriate flood risk assessment that demonstrates:
  - (i) The development proposed will not increase flood risk elsewhere and, if practicable, will reduce overall flood risk;
  - (ii) The development proposal includes measures to minimise flood risk to people, property, the economy and the environment as far as reasonably possible;
  - (iii) The development proposed includes measures to ensure that residual risks to the area and/or development can be managed to an acceptable level as regards the adequacy of existing flood protection measures or the design, implementation and funding of any future flood risk management measures and provisions for emergency services access; and
  - (iv) The development proposed addresses the above in a manner that is also compatible with the achievement of wider planning objectives in relation to development of good urban design and vibrant and active streetscapes.

The acceptability or otherwise of levels of residual risk should be made with consideration of the type and foreseen use of the development and the local development context.

Note: See section 5.27 in relation to major development on zoned lands where sequential approach has not been applied in the operative development plan.

Refer to section 5.28 in relation to minor and infill developments.

1. The development lands have not been zoned by Tipperary County Council.
  - i. The LAP zoning (Annex G) shows that the development is located outside of the any, e.g. Templemore Local Area Plan Zoning.
  - ii. However, Figure 8.13. Suitability of wind farm development for Tipperary Co. Co. and Figure 8.14. Map 2 Wind Energy Policy Areas (in Annex F) suggest that the site is **within Areas open for consideration for New Wind Energy Development**
2. The proposal has been subject to an appropriate Flood Risk Assessment:
  - i. Annex H - HEC-RAS output tables and Figure 8.11-Figure 8.12 show detailed comparison in water levels between existing and design river system for Q<sub>100cc</sub> and Q<sub>1000cc</sub> respectively. For Q100cc the increase in water levels is +0.01m on average, whilst for Q1000cc even some reduction in water levels is evident. The scoping process showed that the site area does not act as an effective floodplain due to relatively low flow velocities and higher ground elevations at the site. The low flow velocities at the proposed site are confirmed in the hydraulic model. Comparison of flow velocities implies that there will be no increase in the potential for erosion, which was demonstrated by insignificant flow velocity increases. Calculations of the pre- and post-development peak run-off flow rate gave an increase in flow to the river of 0.73m<sup>3</sup>/s for the critical rainfall event, and this relatively low flow (relative to river flows of up to 41m<sup>3</sup>/s) will have no effect on water levels. However SuDS design was proposed to mitigate increase of peak flood flows. Flood hydrograph comparison showed small increase or even reduction in peak flood runoff for Q<sub>100cc</sub> and Q<sub>1000cc</sub>. Therefore, on the basis of performed calculations, it can be concluded that the site development **will not increase flood risk on the site or elsewhere**.

- ii. A design measures to minimise flood risk includes design of a high level flood terrace, e.g. turbine hardstands with a 0.5m freeboard for floor levels with ramps to the wind farm road network which is to be finished to exiting ground levels. With the proposed measures the **flood risk to people, property and the environment is minimised** as far as reasonably possible. A comparison of water levels and flow velocity in the channel, between existing and design river system for Design Event 1 comprised 100 years (1% AEP) flows with included climate change of the Suir river and Eastwood stream imply that there would be no change in water levels and in flow velocities. This means that all normal river flow remains unaffected by the proposed flood protection works, and ensures that the existing river main channel remains intact. Therefore, it can be concluded the proposed flood mitigation measures **minimise flood risk to people, property and the environment** as far as reasonably possible.
- iii. According to the flood extend maps, emergency access and egress to and from the site is provided on the east side of the development via the local road L7039 and at the west side from N62 road. Both roads, e.g. access and egress location being outside flood Zone A and B. The proposed finished floor levels of hardstands ensure that the flooding of buildings that are part of Wind Farm are not affected and with on-site road network levels that remain at levels of existing ground ensure that **residual risks to the development can be managed to an acceptable level and that flooding elsewhere is mitigated**.
- iv. The development flood alleviation measures in the form of a simple raised terrace and raised floor levels do not involve any major deviations from what would be considered good urban design.

According to the presented results, it can be concluded that the requirements of Justification Test Part 2 are **satisfied on all defined criteria**.

## 6.7 FLOOD RISK BALANCE SHEET

Flood-risk indicator	Ultra-positive ++	Positive +	Neutral	Negative	Ultra-negative
<i>Is the development within existing flood-risk area?</i>					Risk area within flood zone A
<i>What are the scale and nature of flood risks?</i>	Understood, easy to warn	Predictable			
<i>What scale of residual risk measures will be required?</i>	Measures could eliminate risk to development				
<i>How will egress and access be assured? What will be the emergency planning impact?</i>	Emergency access and egress ensures safe evacuation for 0.1% AEP flow	Hardstands are designed with FFL 1.0m above 0.1% AEP flow levels			
<i>Will there be a change in number of people at risk?</i>			No increase or increase of people at risk		
<i>Will there be a change in number of properties at risk?</i>			Neutral impact		
<i>Will there be an impact of the mitigation measures elsewhere?</i>			Neutral impact		

## 6.8 ENVIRONMENTAL ENHANCEMENT

It is proposed to restore an approximately 240m segment of the Eastwood River within the project site. The Eastwood River within the Project Site is currently in poor condition. It has been straightened and lacks good quality in-stream or riparian habitat. It is proposed to restore appropriate pattern, profile and dimension to the channel with a view to improving stability of the channel and restoring in stream habitat. It is also proposed to establish a natural wooded riparian buffer and to exclude livestock from accessing the restored channel.

The restoration reach is currently approximately 240 meters in length with no sinuosity. It is proposed to construct a new meandering channel with a length of approximately 299m. This will result in a channel sinuosity of approximately 1.32m/m. The new channel (Figure 6.19) will have an average slope of 0.0026 m/m and a bankfull width of 4m. A full assessment on impact of environmental enhancement with details of the concept stream design are provided in Fluvio R&D Ltd. Hydraulic Assessment Report [2]. The Report [2] confirms that impact on the proposed restoration works on the downstream area is zero with slight improvement of flood levels and natural flow conditions locally.

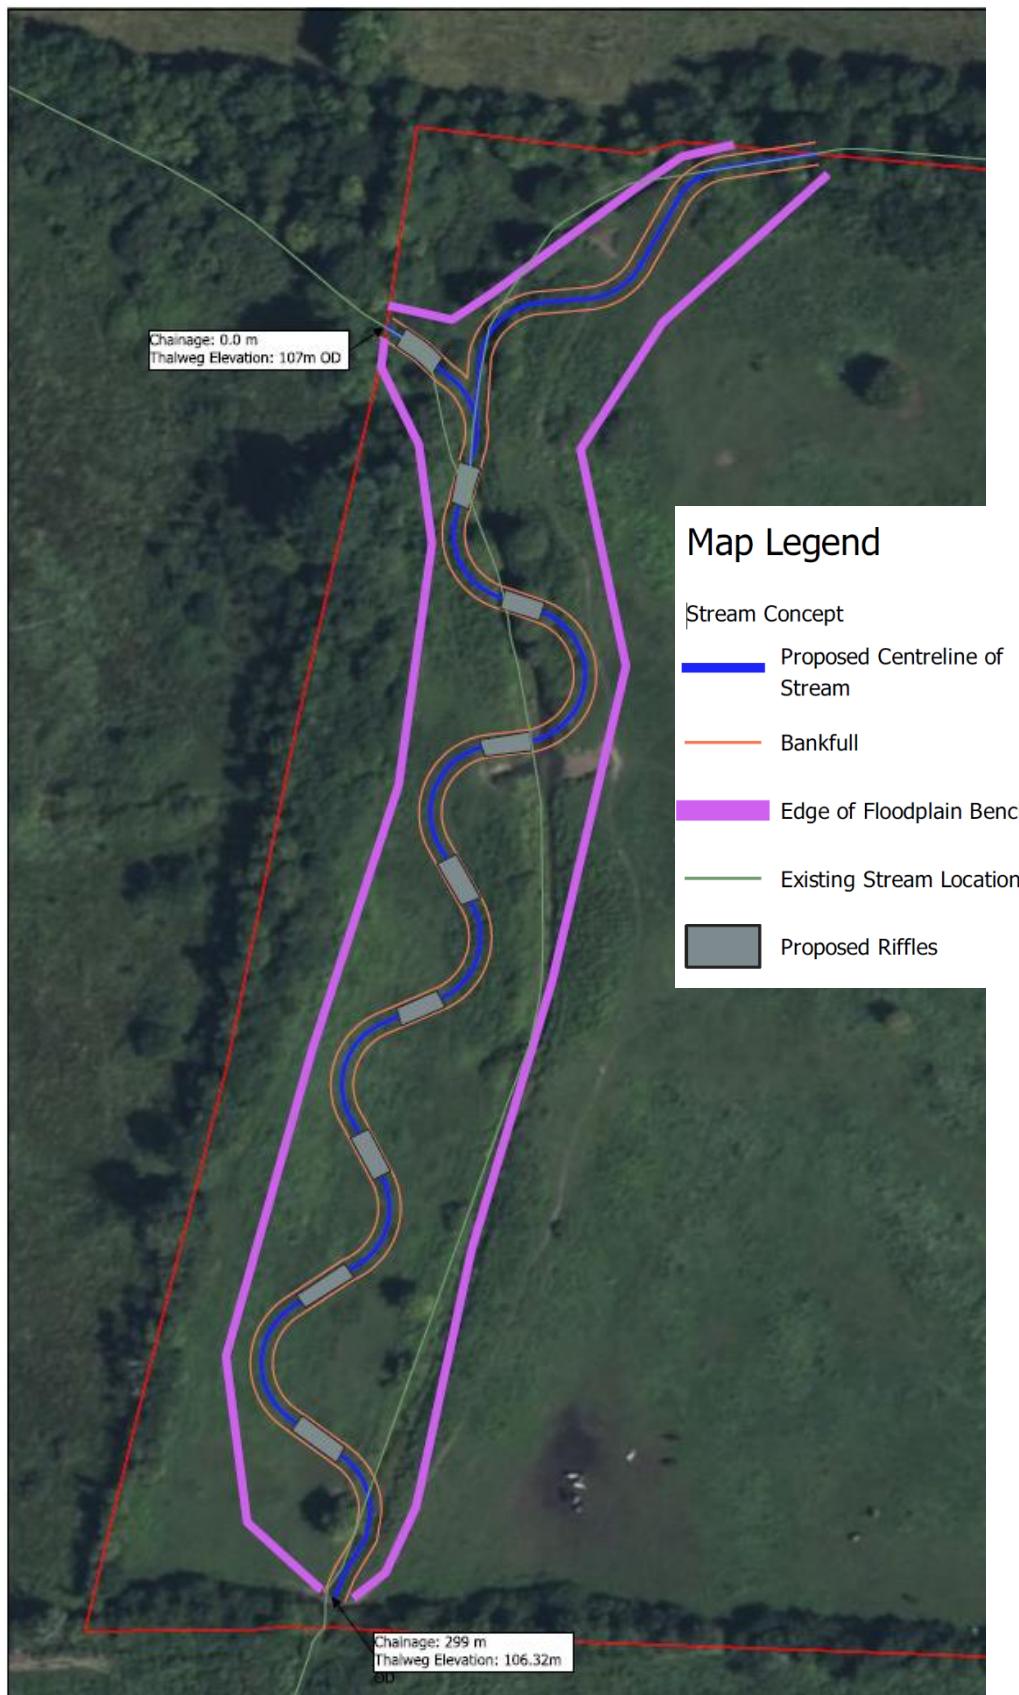

Figure 6.19. Environmental enhancement of Eastwood River reach.

## 6.9 CONCLUSIONS

1. In accordance with the OPW and the Department of the Environment, Heritage and Local Government Guidelines „The Planning System and Flood Risk Management - Guidelines for Planning Authorities“ from November 2009 [1] a flood risk assessment was carried out in three stages

**Stage 1 - Flood risk identification**

**Stage 2 - Initial flood risk assessment.**

**Stage 3 - Detailed flood risk assessment**

2. Stages 2&3 required hydrological and hydraulic analyses as follows:
3. The  $Q_{100cc}$ , and  $Q_{1000cc}$  (including a climate change factor of 1.2) flood flows were obtained from our FSU hydrological study and have the following values  $41.98m^3/s$  and  $53.02m^3/s$  respectively for total catchment area ( $95.619km^2$ ). The drainage of the windfarm site is complex involving two main river channels viz. the River Suir and Eastwood fed by a series of smaller stream and drainage channels. The hydrological model used reflects this complexity and is characterized by a network of Hydrological Estimation Points (HEPs) as described in Table 5.1.
4. A detailed river and bridge survey was carried out which were used to develop a digital elevation model of the river and floodplain. The model did not include any detail on the end masts due to the fact that their relatively small footprint is insignificant in relation to the flow and storage of the huge area of the floodplains.
5. An unsteady flow analysis was required for the FRA to assess the development impact on storage and consequently a number of hydrographs for each of the constituent rivers, stream and channels were developed. The 1D2D hydraulic model HecRas v6.2 was created for Existing and Design River System. The 1D model covers a reach of c. 16km, defined by 564 cross sections and a 28 bridges/culverts (Existing river system model contains 22 bridges). The 2D model covers an area of  $10km^2$ .
6. The following results were obtained for stages 2 & 3
  - a. The Highest predicted water levels are for +0.01m higher than existing water levels. The lowest predicted (design) water levels are for -0.07m lower than existing water levels.
  - b. The results from the simulations showed that there is no change on the longitudinal profile water levels of the  $Q_{100cc}$  and  $Q_{1000cc}$  floods.
  - c. The flow velocities throughout the site range between 0.5m/s and 2.5m/s for the extreme flood event. These velocities are not considered to be of major concern.
  - d. The impact of the development of the storage capacity of the windfarm site was assessed and was demonstrated to be minor by comparing the hydrographs for existing and design river systems at a number of locations and at the downstream end of the site as shown in Figure 6.16 and Figure 6.17.

7. The development design is influenced by the above results as follows:
  - a. Floor levels in the development should be set at a level above water levees for  $Q_{1000cc}$  (Climate Change) + 0.5m additional safety factor freeboard, see Table 6.3.
  - b. The proposed new roads should remain at the same level as existing ground levels in order to ensure natural flow paths over the floodplain and avoid backup of the water.
8. There is an increase in storm runoff from the site as a result of the increase in the impermeable. The increase in flow to the river peaks at a value of  $0.73\text{m}^3/\text{s}$  and is mitigated with the design of SuDS.
9. The question of access and egress from the public road is dealt with as follows:
  - a. Access and egress to and from the site can be provided on the west side via the N62 road or as alternative from the east side of the development via the local road L7039 at an elevation. Both access and egress sites are outside flood zone A and B.
10. Justification test
  - a. The requirements of Justification Test Part 1 - Plan making Justification Test are satisfied on all defined criteria. For the planning elaboration, see the Planning Document.
  - b. The requirements of Justification Test Part 2 - Development Management Justification Test are satisfied on all defined criteria. For the planning elaboration, see the Planning Document.
11. A number of existing culverts throughout the site are function as throttles for flood flows and have the effect of flood flow attenuation. These culverts will not be altered by the wind farm layout design.
12. A number of new culverts have been identified (Figure 6.10) and these can be hydraulically designed using the flows calculated in this study.
13. It is proposed to restore an approximately 240m segment of the Eastwood River to construct a new meandering channel with a length of approximately 299m (Figure 6.19). A full assessment on impact of environmental enhancement are provided in Fluvio R&D Ltd. Hydraulic Assessment Report [2]. The Report [2] confirms that impact on the proposed restoration works on the downstream area is zero with slight improvement of flood levels and natural flow conditions locally.

## 8.4 ANNEX D - Relevant Legislation and Regulations

### 8.4.1 Arterial Drainage Acts

The most important of these acts are the Arterial Drainage Act 1945 and the Arterial Drainage (Amendment) Act, 1995. These Acts provide for the drainage and improvement of land by the execution of works of arterial drainage and the maintenance of these works.

- Weirs: Subject to some exceptions, Section 47 of the 1945 Arterial Drainage Act requires the consent of OPW to erect, enlarge or alter any weir or other like construction in a watercourse where such erection, enlargement or alteration might cause flooding of any land.
- Bridges: Section 50 of the 1945 Arterial Drainage Act requires that no local authority, no railway company, canal company, or other similar body, and no industrial concern shall construct any new bridge or alter, reconstruct, or restore any existing bridge over any watercourse without the consent of the OPW.

### 8.4.2 Environmental Legislation and Regulations

This category covers a wide range of Acts and Regulations, both National and European, dealing with the protection and conservation of the environment. The most important of which are the various Wildlife Acts, Natural Habitat Regulations, and the Water Framework Directive. Significant aspects of the Arterial Water Framework Directive to flood risk management are specified in EU Floods Directive. The new Directive on the assessment and management of flood risks ("Floods Directive") which has been agreed between the EU Parliament and Council will increase the growing emphasis on flood risk management. This Directive is due to be transposed into Irish law by late 2009. This Directive will require that Member States take a long-term planning approach to reducing flood risks in three stages:

1. Member States will by 2011 undertake a preliminary flood risk assessment of their river basins and associated coastal zones.
2. Where real risks of flood damage exist, they must by 2013 develop flood hazard maps and flood risk maps.
3. Finally, by 2015 flood risk management plans must be drawn up for these zones.

These plans are to include measures to reduce the probability of flooding and its potential consequences. They will address all phases of the flood risk management cycle but focus particularly on prevention (i.e. preventing damage caused by floods by avoiding construction of houses and industries in present and future flood-prone areas or by adapting future developments to the risk of flooding), protection (by taking measures to reduce the likelihood of floods and/or the impact of floods in a specific location such as restoring flood plains and wetlands) and preparedness (e.g. providing instructions to the public on what to do in the event of flooding). These three steps are to be repeated in a six-year cycle to ensure that long-term developments are taken into account.

### 8.4.3 Planning and Development Management

The publication of the Guidelines on "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" (November 2009) have emphasised the importance of the FRA. Further information on the Guidelines is available through the document.

Extract from the Guidelines, Box 3.2 - Justification Test:

Where a planning authority is considering the future development of areas at a high or moderate probability of flooding that would include types of development that are inappropriate under the screening process set out in paragraphs 3.6 and 3.7, either in a development plan or development management context, the planning authority must be satisfied that the development is necessary on the basis of all of the following criteria:

#### PART 1

1. The area is within or adjoining the centre\* of a city or town designated for growth in key policy documents such as the National Development Plan, the National Spatial Strategy, any Regional Planning Guidelines in force, planning guidelines/directives under Sections 28/29 of the Planning and Development Act 2000 and/or an operative City/County development plan which has been adopted taking adequate account of these guidelines.
2. The area comprises significant previously developed and/or underutilised lands within the urban envelope.
3. Development of the area is essential to facilitate regeneration or town and city centre expansion, as demonstrated in city and county development plans that have been assessed in accordance with these guidelines.
4. Strategic Environmental Assessment has been undertaken, where applicable, taking full account of flood risk.
5. There are no reasonable and available alternative development areas or sites that meet the wider strategic policy requirements as outlined at 1 above, within low or lower flood probability areas.

#### PART 2

If the requirements of Part 1 are satisfied, then the following additional detailed criterion should also be met. The development has been the subject of a sufficiently detailed flood risk assessment, as appropriate to the nature and scale of the development, and the potential risk that may arise, which demonstrates that:

- a) the development will not increase flood risk elsewhere and, if possible, will reduce overall flood risk;
- b) the development proposal includes measures to minimise flood risk to people, property and the economy and the environment as far as reasonably possible and to ensure that residual risks to the area and/or development can be managed to an acceptable level as regards the adequacy of existing flood protection measures or the design, implementation and funding of any future flood risk management measures.

## 8.5 ANNEX E - NATIONAL FLOOD POLICY

The current Irish National policy on flood risk is outlined in the OPW document "OPW Planning and Development Flood Policy" published on [www.flooding.ie](http://www.flooding.ie). The document states that development should not itself be subject to an inappropriate risk of flooding nor should it cause or exacerbate such a risk at other locations, which is stated through the following guidelines:

- 1. Development that is sensitive to the effects of flooding will generally not be permitted in flood prone or marginal areas.** Preventing such development, where flooding would result in significant hardship, financial losses or costs, will avoid increasing the existing level of risk and will protect the proposed new development from the human (stress and ill-health, for example) and financial costs of flood events. It will also eliminate or reduce expenditure on flood protection measures and compensation.
- 2. Appropriately designed development, which is not sensitive to the effects of flooding, may be permissible in flood plains provided it does not reduce the flood plain area or otherwise restrict flow across floodplains.** Examples of such development might include park areas, sports pitches, certain types of industry, warehousing, etc. designed to be flood resistant and/or insensitive. Such development should only be permitted provided it incorporates adequate measures to cope with the ever-existent flood risk, e.g. adequate drainage systems, safety measures, emergency response facilities and/or warning and response systems and where it is considered that flooding would not result in significant hardship/financial loss or cost.
- 3. Development must so far as is reasonably practicable incorporate the maximum provision to reduce the rate and quantity of runoff, e.g.:**
  - a. Hard surface areas (car parks, etc.), should be constructed in permeable or semi-permeable materials.
  - b. On site storm water ponds to store and/or attenuate additional runoff from the development should be provided.
  - c. Soak-aways or french drains should be provided to increase infiltration and minimise additional runoff.

Such sustainable design/construction measures are desirable in most areas and essential in floodplains, areas liable to flooding, and areas where the conveyancing capacity of watercourses is marginal. In all of these cases development that reduces the rate of absorption or increases the rate of runoff increases the risk of flooding of lands and properties downstream.
- 4. For developments adjacent to watercourses of a significant conveyance capacity any structures (including hard landscaping) must be set back from the edge of the watercourse to allow access for channel clearing/maintenance.** A setback of 5m-10m is required depending on the width of the watercourse.
- 5. Development consisting of construction of embankments, wide bridge piers, or similar structures will not normally be permitted in or across flood plains or river channels.** Such structures restrict/obstruct flow and increase the risk of flooding to property and land upstream. If it is considered necessary, in exceptional cases, to permit such structures, they should be designed to minimise and/or compensate for any potential negative effects.
- 6. All new development must be designed and constructed to meet the following minimum flood design standards:**
  - a. For Urban areas or where developments (existing, proposed or anticipated) are involved - the 100 year flood.
  - b. For Rural areas or where further developments (existing, proposed or anticipated) are not involved - the 25 year flood.

- c. Along the Coast and Estuaries - the 200 year tide level.
- d. Where streams open drains or other watercourses are being culverted – the minimum permissible culvert diameter is 900mm. (Access should be provided for maintenance as appropriate.)

The application of higher design standards may be appropriate in certain cases where the level of risk and/or uncertainty warrant it e.g. hospitals or other emergency services, main roads, chemical plants, cultural repositories, areas of karst etc.

7. **A flood impact assessment and proposals for the storage or attenuation of run/off discharges** (including foul drains) to ensure the development does not increase the flood risk in the relevant catchment **must accompany applications for Planning Permission for development of areas exceeding 1 hectare.**
8. **A certificate from a competent person that the development will not contribute to flooding** within the relevant catchment must accompany applications for Planning Permission for development of areas of 1 hectare or less.

## 8.6 ANNEX F - LOCAL POLICY ON FLOOD MANAGEMENT

### 8.6.1 Renewable Energy Strategy from Draft Tipperary County Development Plan 2022-2028

Four main strategic renewable energy aims of Tipperary county council development plan are set as:

#### **1 A low Carbon Future for Tipperary**

The White Paper 'Ireland's Transition to a Low Carbon Energy Future 2015-20304 sets out a national objective for a low carbon economy with reduced green house gas (GHG) emissions and greater investment in renewable energy technologies. This Renewable Energy Strategy recognises that Ireland (and Tipperary) is a long way off meeting its own energy demands from renewable resources, and it is recognised that significant and immediate commitment to energy (and better energy efficiency) is now required. Continued support for investment in energy production in Tipperary will confer economic advantages in the form of jobs and investment. In addition to meeting its own energy needs, Tipperary will benefit through its contribution to national renewable targets, in a renewable energy framework that will also ensure the protection of local environmental assets. It is strategic aim of this Renewable Energy Strategy to facilitate a low-carbon future in Tipperary by supporting the sustainable development of the renewable energy sector in Tipperary.

#### **2 Achieving Climate Change Adaptation**

There are two main policy responses to climate change: mitigation and adaptation. Mitigation addresses the root causes of climate change, by reducing GHG emissions, while adaptation seeks to lower the risks posed by the consequences of climatic changes. This Renewable Energy Strategy will facilitate the mitigation of climate change by supporting renewable energy sources as an alternative to fossil fuels thereby reducing GHG emissions.

#### **3 Low-Carbon Economy and job Creation**

The Council is committed to employment creation as a direct result of a policy to secure better investment in renewable energy and energy efficiency in Tipperary. This commitment is also reflected in the Council's Local Economic and Community Plan (LECP) with a key objective to improve the sustainability of the county's energy use to enable sustainable economic development. This Renewable Energy Strategy supports the objectives of the LECP as they relate to a green economy and it is expected that the development of a sustainable energy base along with investment in efficiency will confer an economic advantage to the county in the form of jobs and investment.

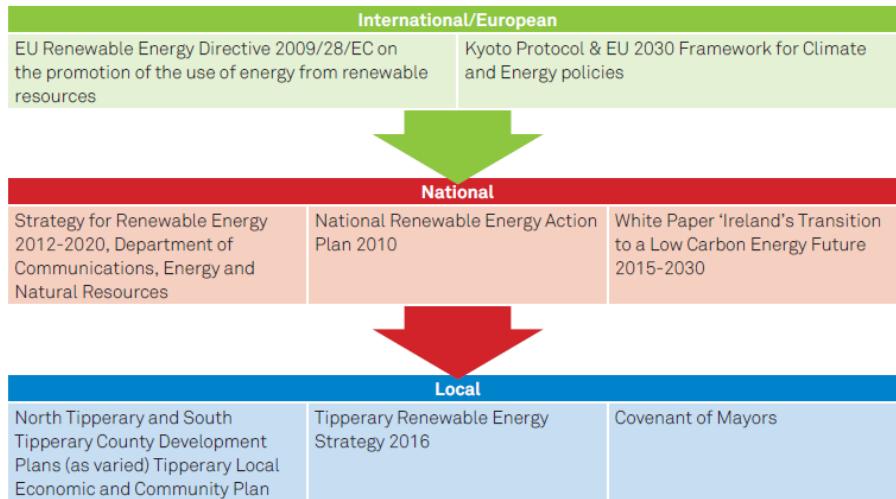

#### **4 A Strategic Planning Framework for Renewable Energy**

It is intended to put in place a planning and regulatory framework for renewable energy development in Tipperary to provide certainty and clarity to both investors and communities alike and to ensure consistency in planning decisions. In order to achieve this objective, the Council is mindful that renewable energy resources, catchments, infrastructure and in many cases, new developments, may extend across county boundaries. In this respect, this Strategy was prepared having consideration to the energy and environmental policies of adjoining counties.

#### **Policy overview and Local policy**

The Renewable Energy Strategy is set in a hierarchy of international and national legislation which

provides the statutory basis for planning policy for the development and use of renewable energy resources and for the protection of the environment

### 2.5.1 County Development Plan (As Varied)

There are two County Development Plans in place in Tipperary:

- The South Tipperary County Development Plan 2009 (as varied)
- The North Tipperary County Development Plan 2010 (as varied)

The County Development Plans (as varied) provide a strategic, cohesive and consistent planning framework for the full county in all areas including energy and energy efficiency. The Renewable Energy Strategy has been incorporated into the County Development Plans by way of Variations number 3 and will supplement and inform the current county planning framework as set out and will go forward to underpin and support any review of the County Development Plans.

### 2.5.2 Sustainable Energy Action Plan for Tipperary

In line with the commitment to the Covenant of Mayors, the Council, with the support of the TEA will prepare a Sustainable Energy Action Plan (SEAP) for the county. It is expected to be completed in 2016 and will set out a range of actions aimed at reducing CO<sub>2</sub> emissions in the county. The preparation of a SEAP is a key action of this Strategy.

### 2.5.3 Local Economic and Community Plan

The LECP 2015 was developed by the Tipperary Local Community Development Committee (LCDC) and Tipperary County Council's Economic Development and Enterprise Strategic Policy Committee. It contains high level goals and actions to drive economic, social and community development in the county over the next six years and was developed in consultation with key stakeholders, the broader community and business interests.

**It is a high level economic objective of the LECP to improve the sustainability of the County's energy use by supporting enterprises in energy, efficiency reduction/improvements and by growing the renewable energy enterprise sector.**

Strategic Actions are set out below:

- Maximise competitiveness of businesses through best practice energy management by increasing awareness of supports available,
- Provision of energy management training across all sectors e.g. manufacturing, tourism, retail, agriculture, etc. as appropriate,
- Piloting of energy programmes, sustainable transport programme etc,
- Support and encourage public sector bodies to achieve current ISO Energy Standard, and,

- Support research, education & training on sustainable energy technologies.

#### **Section 2.5.4 Adjoining Counties**

Tipperary shares common boundaries with the following counties; Cork, Limerick, Clare, Galway, Offaly, Laois, Kilkenny and Waterford. Each of these counties share a common purpose to facilitate renewable energy developments, whilst protecting environmental assets. The Council will endeavour to manage and support renewable energy development in consultation with adjoining local authorities.

### **Tipperary Energy Case Studies**

Tipperary has been a leader in the area and there have been a number of local and community-led renewable energy and energy efficiency schemes in the county that demonstrate the benefits of investment in the area and that will be used as examples for further investment. The following are examples of:

- Direct Community investment in energy
- Direct Community investment in energy efficiency
- Local Authority investment in energy
- Community Gain Scheme

#### **3.5.1 Direct Community Investment in energy - Templederry Wind Farm**

In 2001, the local community in Templederry sought to investigate ways to increase employment and investment in their area. Renewable energy was examined as an investment opportunity and 'Templederry Energy Resources' was set up and 30 shares in the company were allocated. The TEA and the North Tipperary LEADER assisted in the planning and development phase of a new wind farm consisting of two wind turbines. This entailed assessment of the wind resource in the area, acquiring finance, a connection to the national grid and securing planning permission. The group is now producing enough electricity to power 3,500 houses per annum.

#### **3.5.2 Community Investment in Energy Efficiency - Drumbane/Uppercurch**

Upperchurch/Drombane is a community of around 1,200 people and 400 houses. A community team called the Drombane Upperchurch Energy Team (DUET) surveyed the areas energy spend in 2011 and found that the community was spending €1 million per annum on domestic energy (heating and electricity). Over two years with the help of the TEA, Limerick Institute of Technology and North Tipperary LEADER Partnership, retrofit works were carried out on 50 homes and two community halls by local contractors, and retrofitting work continues. Householders have lower energy bills, and the local economy has benefited from the project.

#### **3.5.3 Local Authority investment in energy - Council Photovoltaic scheme**

In 2014, in conjunction with the TEA the Council installed solar photovoltaic (PV) panels on 9 local authority buildings to provide renewable electricity and reduce demand by 171,000 kWh annually. The buildings include 3 Civic Offices, 2 Fire Stations, 2 Libraries, a Machinery Yard and a Leisure Centre.

All photovoltaic arrays began generating power in early November 2014 and have an expected life in excess of 25 years. The power produced equates to an average annual reduction in electricity demand of approximately 11% and the Council is saving over €27,000 per annum on its electricity bills with a payback of 7 years.

#### **3.5.4 Community Fund - Lisheen Wind Farm, Co Tipperary**

A number of wind energy projects in Tipperary have entered into agreements with communities to deliver particular and agreed financial benefits to the local community. Such community funds can empower communities to have direct benefit from renewable energy projects while also contributing to a low carbon economy.

Lisheen Wind Farm is operated by Brookfield Renewable Ireland and is located 15km north of Thurles, Co. Tipperary and is located within the grounds of a zinc mine. During the design process

and after discussion with the local community it was agreed to set up a Community Fund known as the Moyne/Templeouhy Community Trust Fund. This was established in 2009 on commissioning of the windfarm. Whilst this is not an example of direct community investment, it is an example a partnership with the local community who has, through this trust fund been able to invest in a number of community projects. In this respect, the Irish Wind energy Association (IWEA) supports the provision of financial contributions by wind farm operators to local communities and have prepared 'Best Practice Principles in Community Engagement & Community Commitment' 2013 for delivering extended benefits to local communities for wind farm developments of 5 Megawatts (MW) or above.

## 6.5 Wind Energy Strategy

The Tipperary County Wind Energy Strategy contained in Appendix 1, sets out a planning framework for development of wind energy in the county. The Strategy, which has been informed by a LCA and SEA/HDA, identifies areas where wind energy development is 'open for consideration' and where wind energy developments are considered 'unsuitable'. The Strategy also set out the appropriate planning policy and development management standards to support and manage sustainable wind energy development.

### 3.2 Tipperary in the National Context:

According to the Irish Wind Energy Association in 2015 there were 18 operational wind farms in County Tipperary. A total of around 132 turbines have been erected with a generation capacity of approximately 268 MW<sup>1</sup>. To put this in the context of the national picture, just over 11% of the 2400MW wind energy capacity installed nationally was located in Tipperary.

### 3.3 Tipperary Developments to date

Up to February 2016 there have been 94 planning applications in relation to wind energy in Tipperary; 48 applications related to the north of the county and 46 applications related to the south. In County Tipperary overall, 47 applications were granted, 31 have been commenced of which 18 are connected to the grid. 16 have not yet commenced and the planning permission for 3 of these has since expired. As of February 2016, 6 applications are currently under consideration and 42 applications have been refused. Multiple applications per wind farm account for the discrepancy between the numbers of granted and constructed applications and the number of operational wind farms. In terms of turbine numbers, approximately 317 turbines have been permitted, and approximately 203 of these have been commenced. The location of the planning applications overlaid on the existing wind energy development policy areas is shown in Map 1.

#### 3.3.1 South Tipperary Development Plan Area 2009 (as varied)

In the South Tipperary Development Plan area, wind energy development policy has been guided since 2006 by the Landscape Character Assessment covering the upland areas. As of February 2016, 98 turbines have been granted and 80 of these have already been constructed. The majority of these are in areas preferred for wind energy development, approximately 20 are in areas open for consideration (as discussed in section 2.3.2 of this strategy), but within 1km of the preferred areas and approximately 16 turbines were in areas classified as unsuitable for wind energy development. In all granted applications turbine power output has remained below 3MW per individual turbine. In terms of refusals, 8 applications from 21 were in areas preferred for wind energy development, 1 in areas open to consideration and 11 applications in unsuitable areas for wind energy development. This has led to a pattern of distinct clustering of wind energy development in the areas preferred for wind energy development. One of this areas, located in and around the Hollyford Hills and Mountain Mosaic in the Northwest of South Tipperary holds the highest concentration of both operational, granted and submitted applications for wind farms, as shown in Map 1. The other area with clustered projects is located near Slieveardagh Hills Farmland Mosaic in the east of Tipperary.

#### 3.3.2 North Tipperary Development Plan Area 2010 (as varied)

The existing policy on wind energy development in the North Tipperary Development Plan area was based on the North Tipperary Wind Capacity Strategy and Outline Landscape Strategy (2009). These identified areas with adequate wind resources and then differentiated between those deemed suitable for wind energy development and those deemed unsuitable due to scenic, ecological, historic or tourism considerations. This approach did not specifically identify preferred areas for wind energy development. As

of February 2016, 198 turbines from 27 wind energy applications have been granted or are pending (decision awaiting) from which 105 have been commenced. In the areas deemed suitable, approximately 99 turbines have been granted/pending. In areas where wind resource is not adequate but not deemed as unsuitable 66 turbines have been granted (one third of the total) and 33 turbines (one sixth) were granted in areas deemed unsuitable for wind energy development. In all granted applications turbine power output has remained at 3MW or less. In terms of refusals, 21 applications have been refused, 11 of these were in areas deemed suitable for Wind Energy Development with Adequate Wind Resources, 6 in areas deemed suitable but where wind resource is not adequate and 4 applications were in areas deemed unsuitable for wind energy development.

The majority of the applications have been in the Silvermines – Rearcross area and the Upperchurch – Kilcommon area in the west of Tipperary. This development cluster is compatible with the wind energy policy in South Tipperary, where there is an adjacent wind farm development cluster in the Hollyford Hills and Mountain Mosaic area. The remaining wind energy developments are concentrated on the Devilsbit Uplands and the Templemore Plains in the east of the county. The latter area is adjacent to the Kilkenny County boundary and compatible with the Kilkenny wind energy policy of “Acceptable in Principle”. It can be seen from this that the presence of wind energy policy areas has effectively guided the distribution of wind energy development to-date in Tipperary. Over half of the wind energy applications have been in “preferred areas for wind development” and these areas account for three-quarters of the granted or pending applications. The applications in “Areas open for Consideration” were generally granted while conversely around 70% of the applications in “areas unsuitable for wind energy development” were refused.

### **3.4 Future prospects on Wind Energy Developments in Tipperary**

Future projections under the NEEAP/NREAP scenario are targeted to achieve 4000MW of installed wind energy in the RoI. The White Paper: Ireland’s Transition to a Low Carbon Energy Future (2015 - 2030) extends this growth in renewable energy in its vision where Ireland becomes a leader in renewable energy deployment of large and small-scale renewable energy technologies. As individual renewable energy targets are not set out at the county level it is difficult to identify how much wind energy power is to be generated in County Tipperary to meet these the NREAP or subsequent targets.

Tipperary County Council however, fully supports the strategic national goals and recognises the importance of progressing towards the development of a sustainable renewable energy sector.

The assignment of Gate 3 grid connections to accommodate new wind energy developments in County Tipperary have been approved and the approved MW at Gate 3 together with the actual operational capacity and forecasts for 2020. If the forecasted 575MW of wind energy is installed in Tipperary by 2020 by Gates 1, 2 and 3, this would account for c. 14% of the national installed wind energy capacity (assuming the NREAP target of 4,000MW is reached at a national level). This target for 2020 would require the installation of more than double the existing installed capacity in a 5-year period. This reflects the national situation, noted in the 2015 White Paper, where it is calculated that to achieve the 2020 40% target, the average rate of build of onshore wind generation will need to increase to up to 260 MW per year from the current rate of build of about 170 MW per year.

The existing Wind Energy Strategies have actively encouraged and successfully guided Tipperary’s wind energy development to-date. However, there are barriers to its further development (ref Chapter 4 and Chapter 5) that will need to be addressed if Tipperary is to continue to develop in line with the Strategic goals set out by the Department of Communications, Energy and National Resources for 2020. In addition, there have been significant legislative changes in relation to the requirements for Strategic Environmental Assessment (SEA), Environmental Impact Assessment (EIA), Appropriate Assessment (AA) and Flood Risk Assessment (FRA) as well as planning law in the intervening time since the existing strategies were developed. The incorporation of these changes will require amendments to the existing policy areas. The most notable example of this will be the exclusion of the European Environmental Designated sites (Natura 2000) from areas considered suitable for wind energy development.

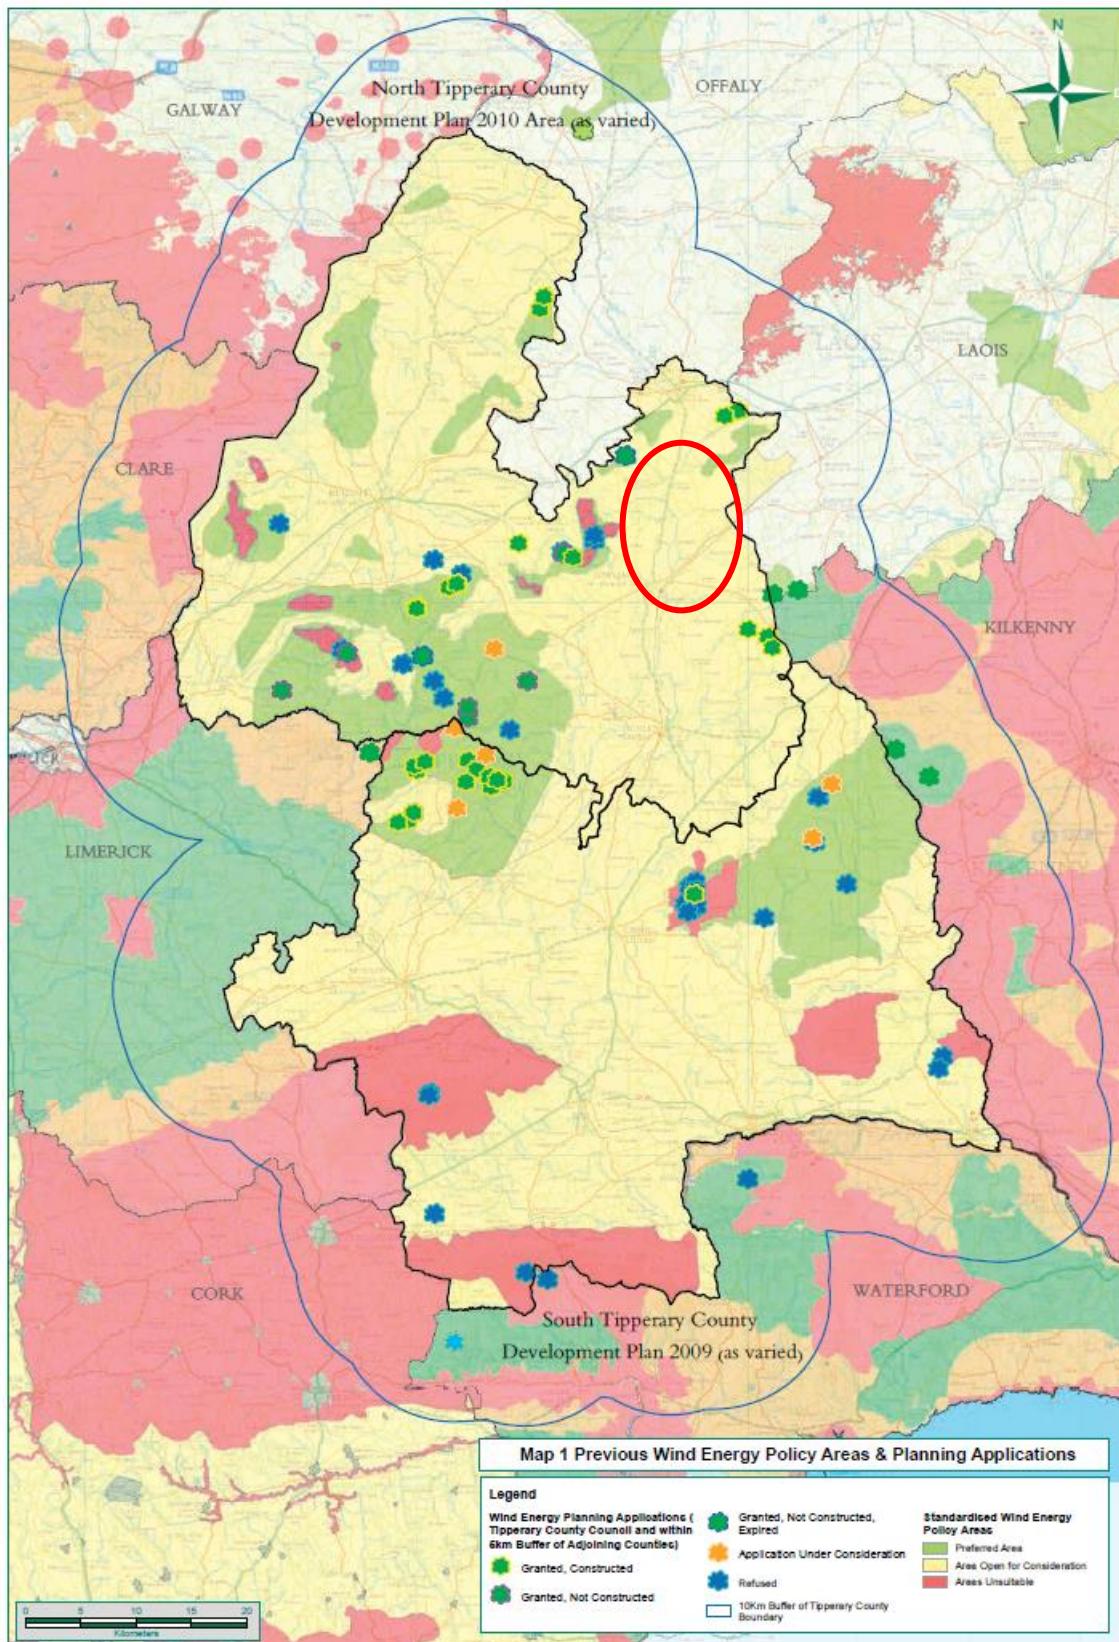

Figure 8.13. Suitability of wind farm development for Tipperary Co. Co.

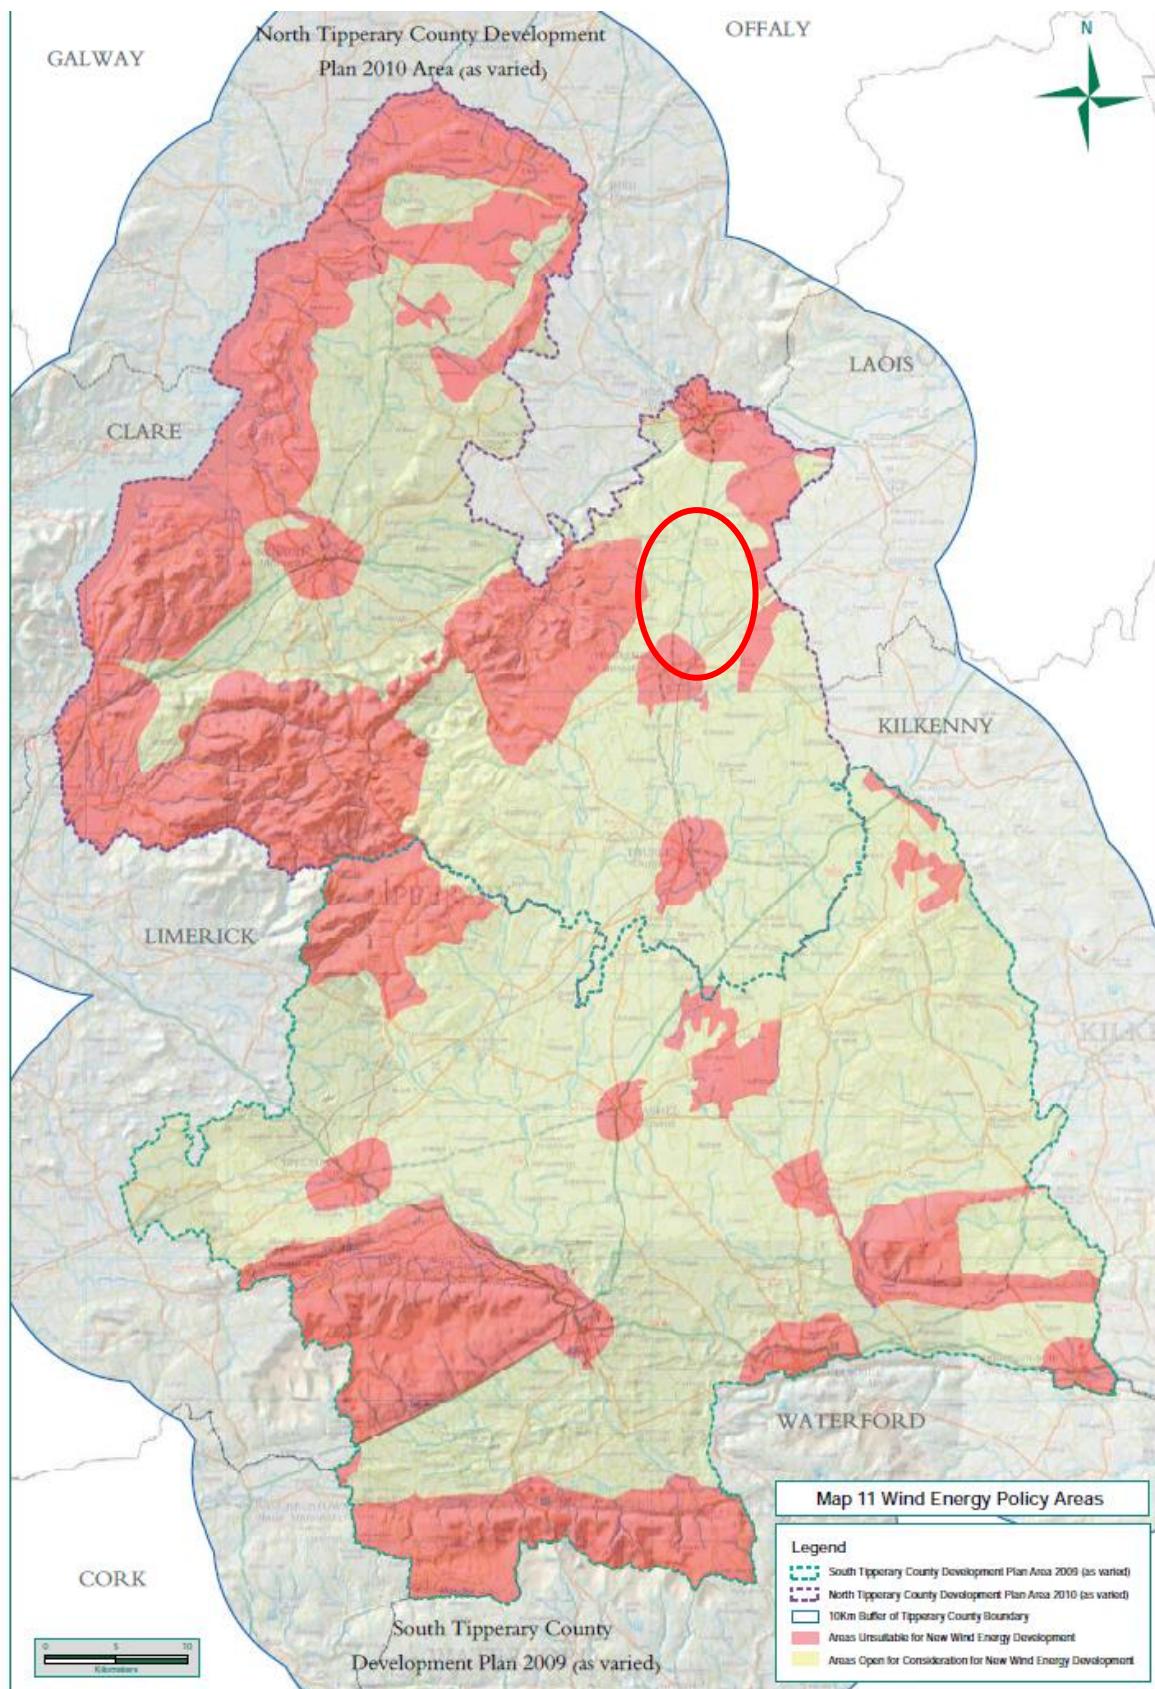

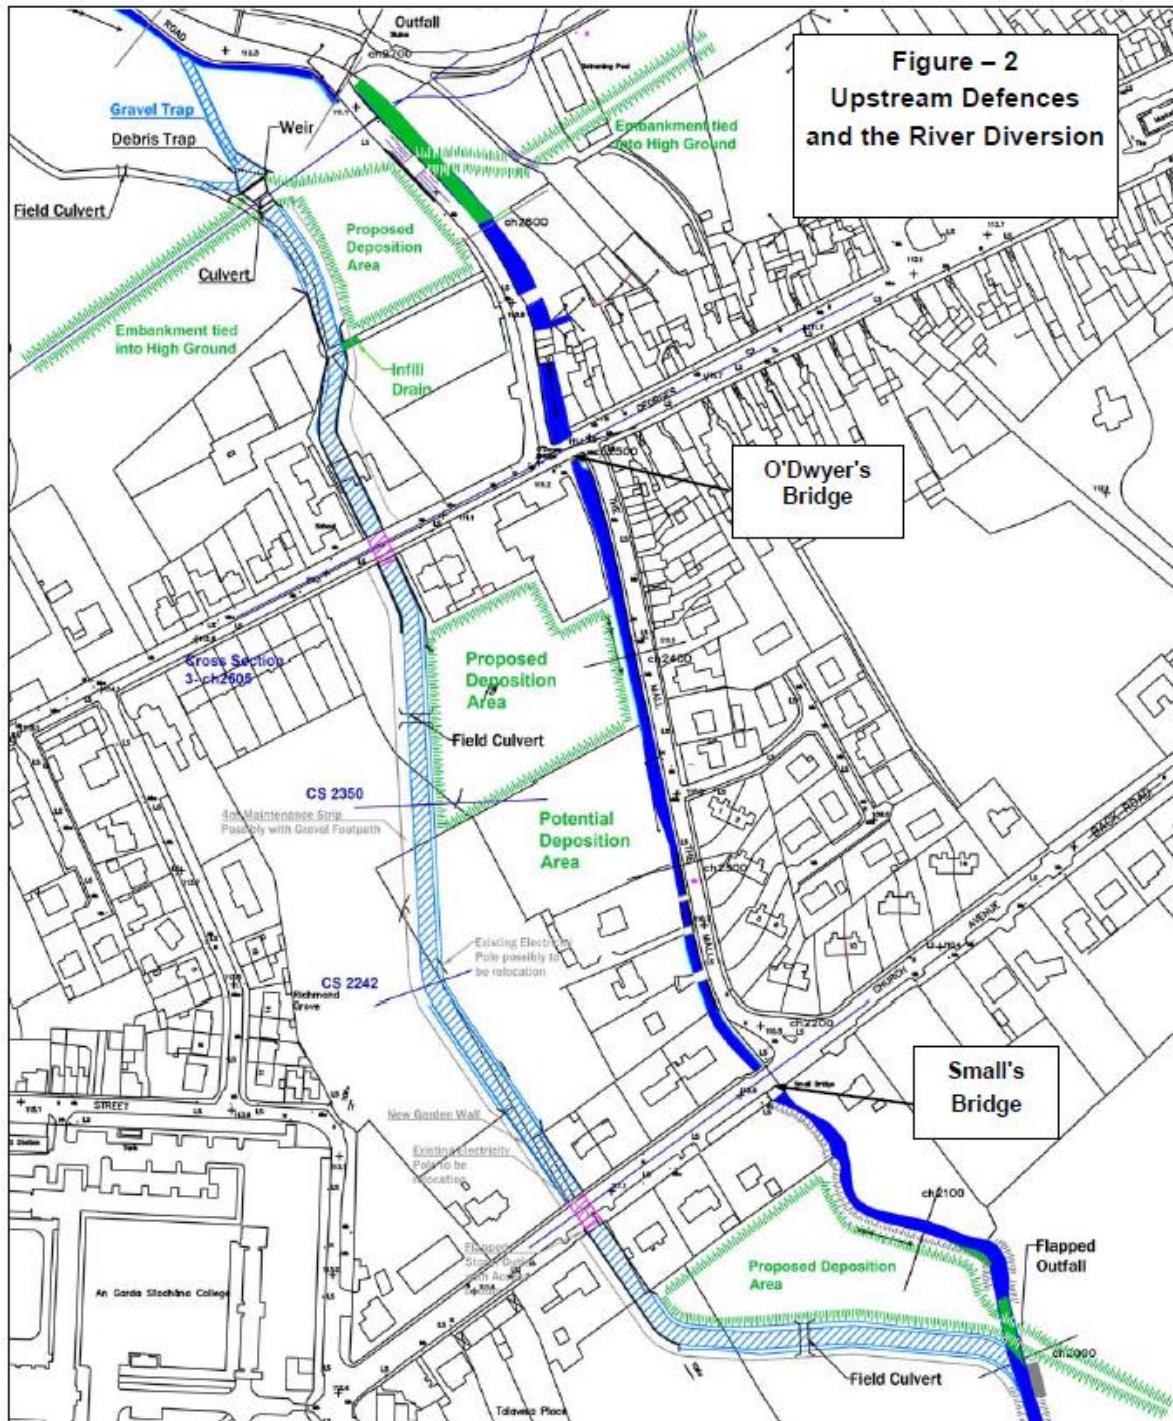

Figure 8.14. Map 2 Wind Energy Policy Areas

## 8.6.2 Templemore Flood Relief Scheme

Templemore, Co. Tipperary Flood relief scheme is focused on works on river Mall only and it does not provide any relevant information for river Suir or Eastwood stream.

## 8.6.3 OPW Flood Risk Management Plan for Suir

Although town of Templemore and surrounding areas are not included in OPW flood risk management plan for Suir because flood relief scheme is to be implemented for the town of Templemore, some guides on Maintenance of Drainage Districts are relevant for the site. This is because the site falls within Arterial drainage district.

**“Existing Measure:** around the proposed Wind Farm development is Maintenance of Arterial Drainage Schemes.

**Outline:** The OPW has a statutory duty under the Arterial Drainage Act, 1945, and the Amendment of the Act, 1995, to maintain the Arterial Drainage and Flood Relief Schemes constructed by it under those Acts.

**Existing Measure: Maintenance of Drainage Districts**

**Outline:** The statutory duty of maintenance for 4,600 km of river channel benefiting from Drainage District Schemes rests with the relevant Local Authorities.”

Abstract from Tipperary County Development Plan of Flood Risk Management for Suir.

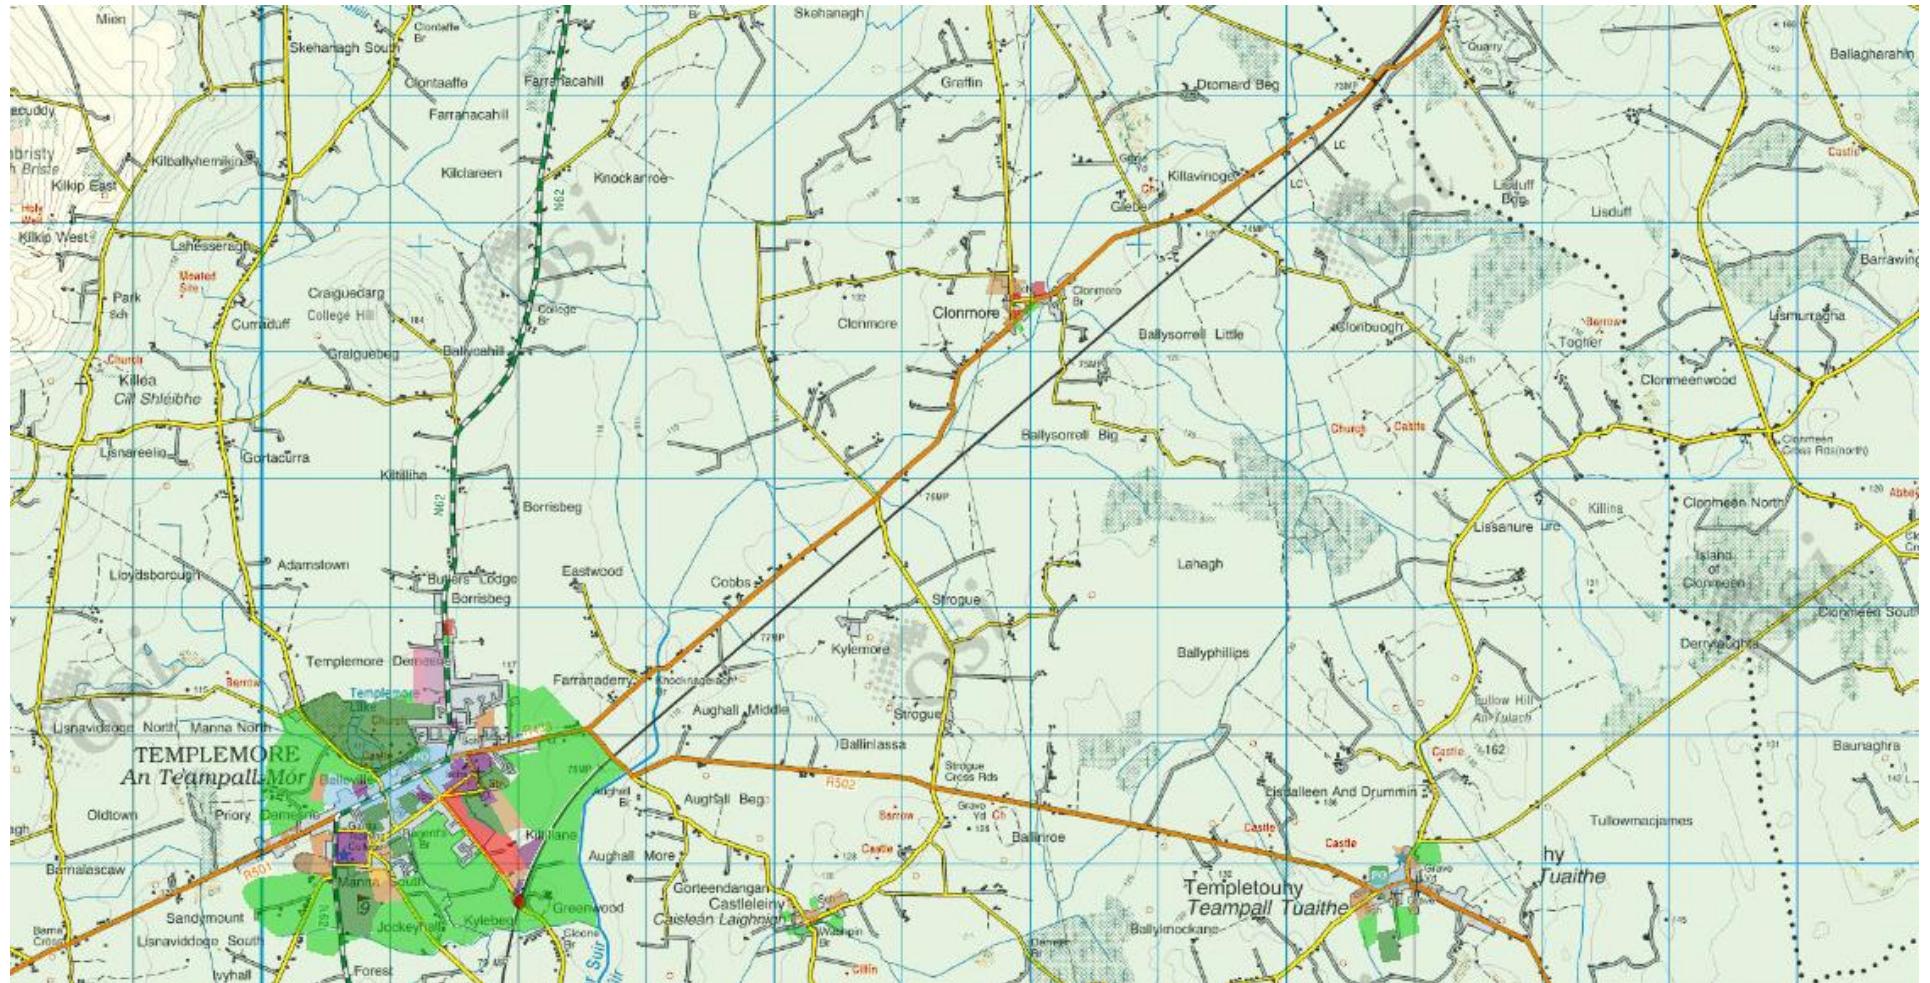

**“7.4.1.8 Protection: Maintenance of Drainage Districts**

There are four Drainage Districts within the Suir River Basin, namely the Templemore DD, Clodiagh DD, Cromoge DD and Farneybridge DD. The local authorities have a statutory duty to maintain the Drainage Districts, and this Plan does not amend these responsibilities to provide additional flood relief. The Plan therefore does not set out additional measures in relation to the maintenance of Drainage Districts.

**7.4.1.9 Maintenance of Channels Not Part of a Scheme**

Outside of the Arterial Drainage and Drainage District Schemes, landowners who have watercourses on their lands have a responsibility for their maintenance. Guidance to clarify the rights and responsibilities of landowners in relation to the maintenance of watercourses on or near their lands is available at [www.flooding.ie](http://www.flooding.ie).”

NOTES:

N/A Data not available

These values are derived from a Depth Duration Frequency (DDF) Model

For details refer to:

'Fitzgerald D. L. (2007), Estimates of Point Rainfall Frequencies, Technical Note No. 61, Met Eireann, Dublin',

Available for download at [www.met.ie/climate/dataproducts/Estimation-of-Point-Rainfall-Frequencies\\_TN61.pdf](http://www.met.ie/climate/dataproducts/Estimation-of-Point-Rainfall-Frequencies_TN61.pdf)

## 8.10 ANNEX J - FSU REPORT

# Flood Estimation Report #13792 (Borrisbeg02)

# 1 Introduction

## 1.1 BACKGROUND AND SITE LOCATION

Fluvio R&D Ltd. was commissioned by Buirios Limited, to undertake a Hydraulic Assessment of stream restoration works (re-meandering) of 300m reach of the River Eastwood as an extension of Flood Risk Assessment (FRA) for a wind farm development at Borrisbeg, Co. Tipperary, Ireland.

This report will assess the flooding risk to the development, adjoining and downstream lands for low, medium and extreme flood flows in accordance with the guidelines published by the OPW and DHELG in November 2009 "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" [1].

In general, this FRA concludes that stream restoration works do not affect flood flows/runoff downstream of the works and locally improve/lower flood levels by enabling additional storage for medium and high flood flows.

The site is located east of the N62 and the townland of Borrisbeg, and north-east of Templemore in Co. Tipperary as shown in Figure 1.1.

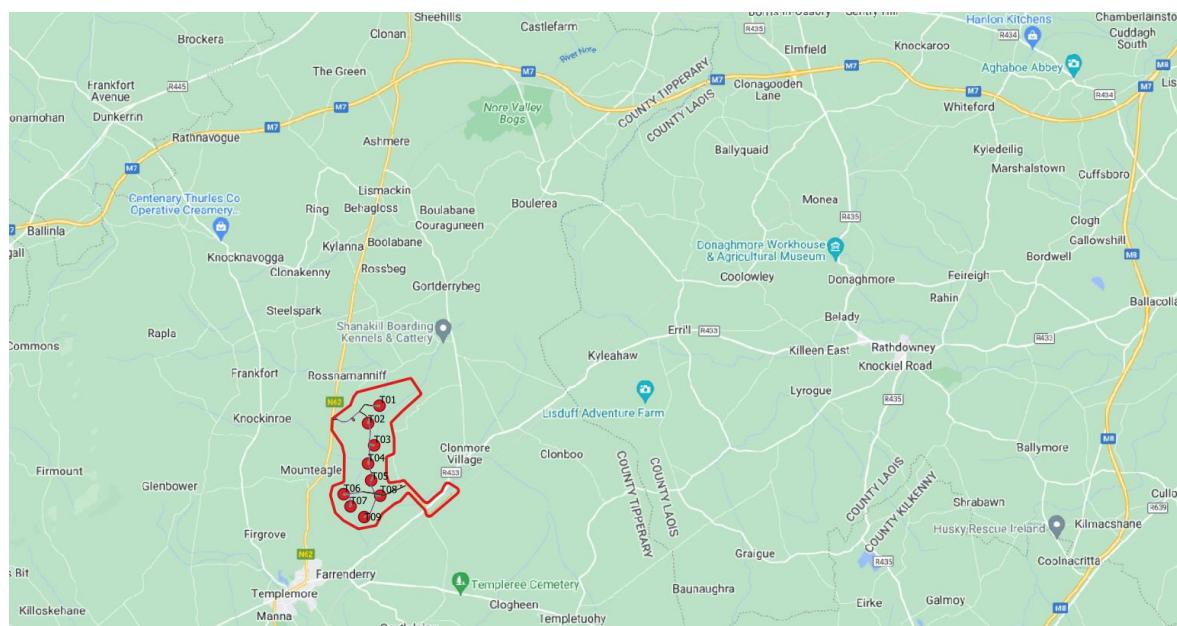

Figure 1.1. Site location.

## 1.2 RE-MEANDERING RESTORATION PROPOSAL

For the purposes of environmental/ecological enhancement within the wind farm site, it is proposed to restore a circa.240m segment of the Eastwood River. From an ecological perspective, the Eastwood River within the project site is currently in poor condition. It has been straightened and lacks good quality in-stream or riparian habitat. It is proposed to restore appropriate pattern, profile and dimension to the channel with a view to improving stability of the channel and restoring in stream habitat. It is also proposed to establish a natural wooded riparian buffer and to exclude livestock from accessing the restored channel.

The restoration reach is approximately 240 meters in length with no sinuosity. It is proposed to construct a new meandering channel with a length of approximately 299m. This will result in a channel sinuosity of approximately 1.32m/m. The new channel will have an average slope of 0.0026 m/m and a bankfull width of 4m.

The 240m of the existing Eastwood River reach within the proposed Borrisbeg Wind Farm (WF) shown in blue box Figure 1.2 is proposed for restoration to create a 299m meandering reach. Previous existing channel is canalised as a straight reach, while the restoration works will introduce a meandering pattern with additional riffle and pool sections as shown in Figure 1.3.

Typical sections of riffle and pool is shown in Annex C.

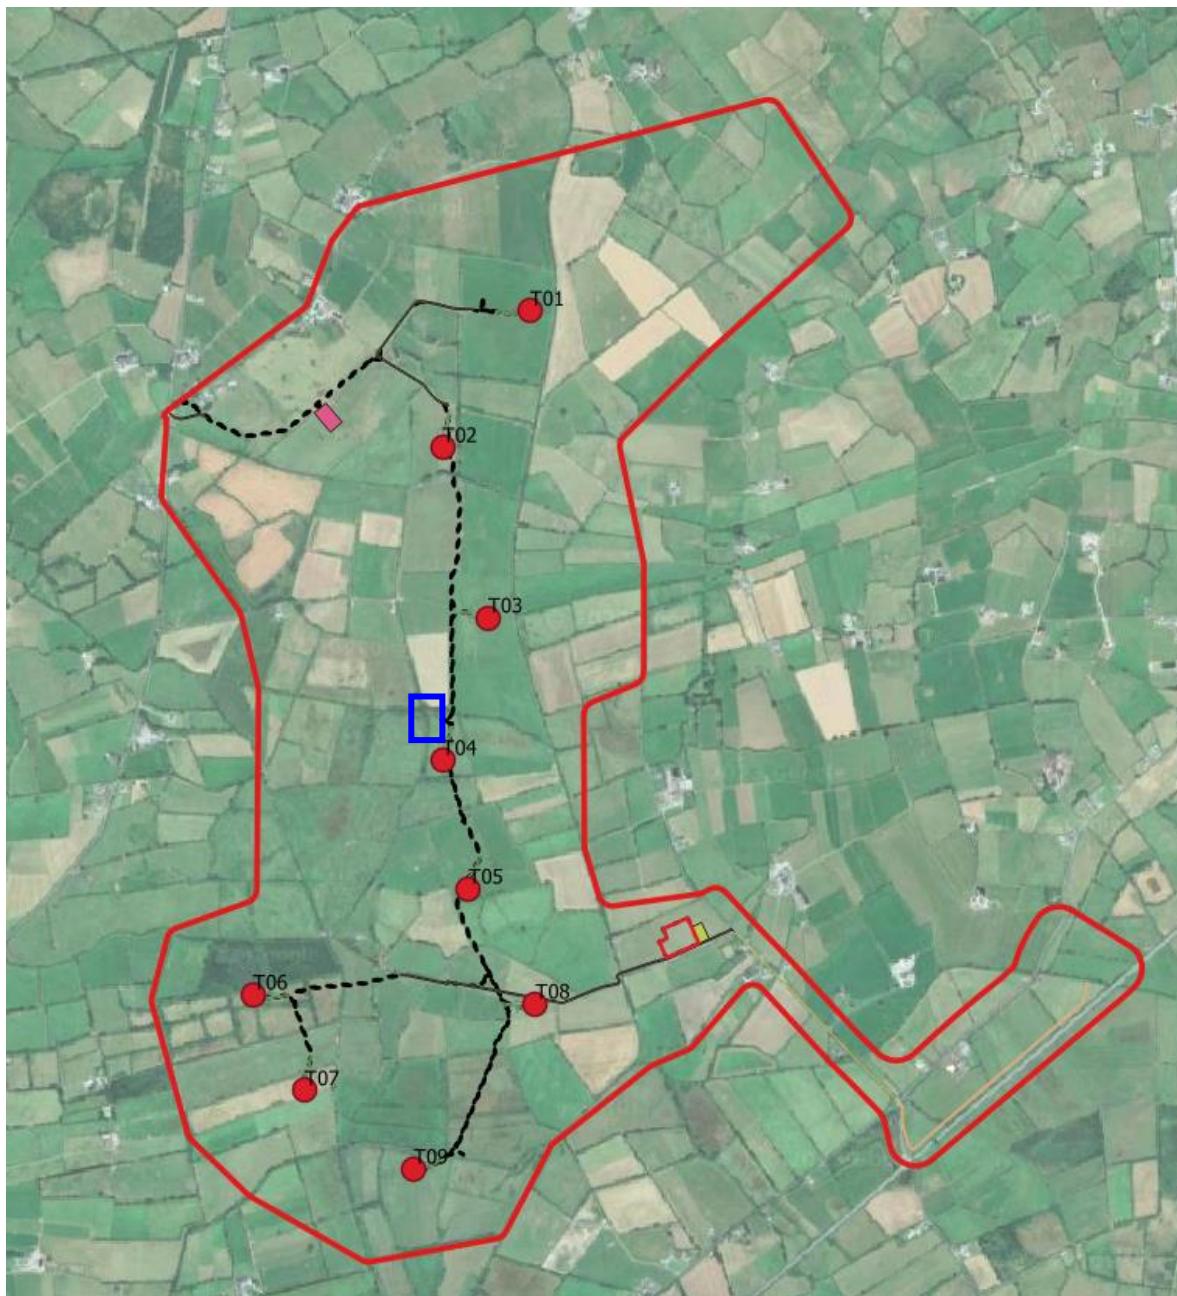

Figure 1.2. Proposed wind farm development.

Figure 1.3. Layout of proposed restoration works in Eastwood River.

### 1.2.1 Scope and objectives

The scope of this report is to provide the information necessary for a planning application by the wind farm (WF) developer, to discharge their responsibilities under the OPW Planning and Development Flood Policy with regard to flood risk constraints and to ensure that the development complies with the flood risk policies within Tipperary County Council's Development Plan [11]. This report has been prepared in accordance with "The Planning System and Flood Risk Management – Guidelines for Planning Authorities" published by OPW and the Department of the Environment, Heritage and Local Government in November 2009 [1]. The aim of the FRA is to:

- Identify the flooding issues associated with the re-meandering proposal (if any) at and adjacent to the site,
- Identify and carry out the studies required to assess the impact of these.
- Design mitigation and flood alleviation measures for the development should issues arise.

The risk assessment covers all sources of flooding, including the effects of run-off from the re-meandering development on flood risk to the vicinity, environs and downstream of the development site. The study involves the use of a previous hydrological assessment to estimate extreme river flows and examines the effect of the proposed development on these and assesses if this will have any significant impact on flooding elsewhere.

## 2 Existing site conditions

The subject site is located in Borrisbeg, Co. Tipperary, Ireland. The site is located east of the N62 road and the townland of Borrisbeg and north-east of Templemore in Co. Tipperary as shown in Figure 1.1.

### 2.1 HYDROLOGICAL FEATURES

A site walkover survey was carried out in April 2022 to establish the pattern of existing drainage and to record existing hydrology features. This was carried out to provide data for the Fluvio Borrisbeg FRA [2]

In summary, the site has a gentle slope in a north – south direction. The surface runoff percolates underground while the excess water is collected by the River Suir, Eastwood Stream and field drains along the site. Identified hydrological features are shown on Figure 2.2.

In total, 22 stream/river crossings have been identified within the site and adjacent to the site boundary and a single levee, these are marked on Figure 2.2 below. Property access culverts/bridges are marked from '1' to '22'. Culvert/Bridge characteristics are provided in Table 2.1. The highest ground level is at the northern part of the site, 113mOD, and the lowest point is in the south-western corner of the site, 107mOD. No local low points were identified during the site walkover. Some marsh areas with surface water ponding are located at the south side of the site where the two rivers become closer and eventually the Eastwood merges with river Suir.

An existing single span Bridge No 17 (Figure 2.1) c. 4m wide acting serving as farm access road from table below is incorporated in the Fluvio 2D hydraulic model [2] as it acts as a throttle on the downstream end of the re-meander reach, and acts as a control point during flood flows, see Figure 2.2 and Table 2.1.

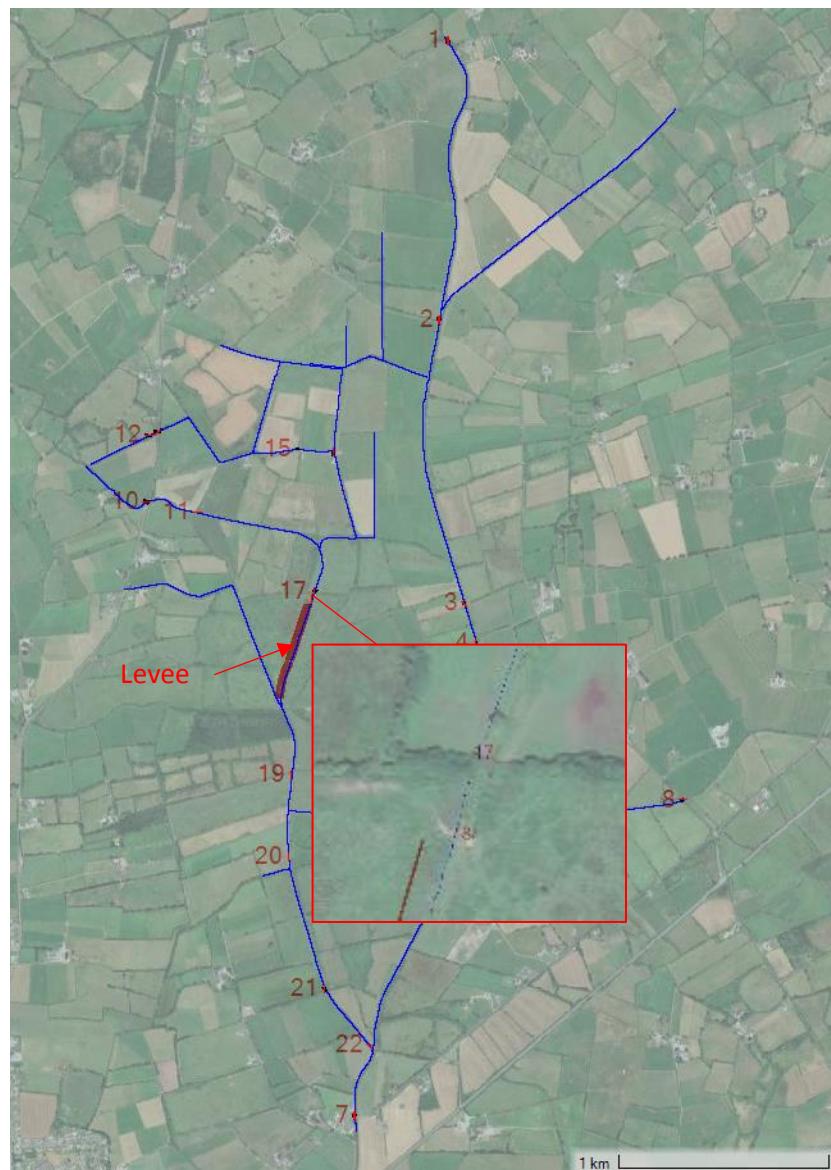

Figure 2.2. Hydrological Features

## 3 Hydrology

The hydrology calculations for this study are taken from the Fluvio Borrisbeg FRA Report [2] using  $Q_{med}$ ,  $Q_{100}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  flood flows. Flows for  $Q_{100cc}$  and  $Q_{1000cc}$  have included climate change factor with increase of 20% . The upstream section of the River Eastwood is explained by Hydrological Estimation points (HEPs) H11 and H14 as described in the Borrisbeg FRA report. The new HEP,  $H11_L$  is introduced in order to provide more detailed input data for the left (east) branch of the stream in the new hydraulic model. The input flows for the left stream branch  $H11_L$  are calculated based on the difference  $H11_L = H14 - H11$ , see figure below.

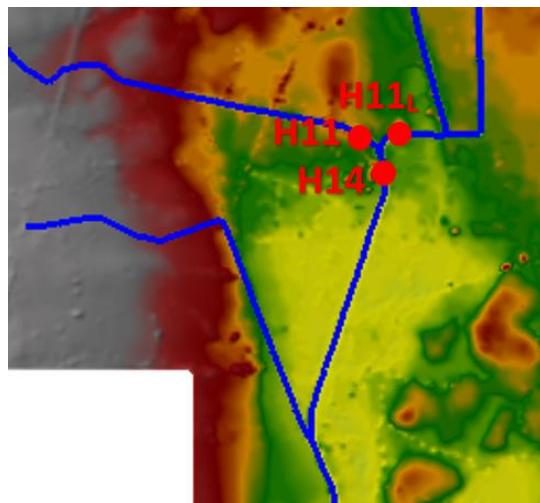

Figure 3.1. Relevant Hydrological Estimation Points (HEP's) for the new hydraulic model.

Each of the tributaries is hydrologically assessed separately and the runoff is calculated for a set of HEPs. The locations of the HEPs are shown in Figure 3-1 above.

The breakdown of the contributing catchment areas and design flow rates for each HEP is given in the Table 1 below.

Table 3.1. Design flows [ $m^3/s$ ] and contributing catchment area [ $km^2$ ] for each HEP.

HEP ID	HEC RAS node	Catchment area [ $km^2$ ]	$Q_{med}$ [ $m^3/s$ ]	$Q_{100cc}$ [ $m^3/s$ ]	$Q_{1000cc}$ [ $m^3/s$ ]
<b>H11</b>	UBC-Right	8.439	1.26	4.32	5.45
<b><math>H11_L</math></b>	UBC-Left	2.791	0.39	1.36	1.71
<b>H14</b>	n/a	11.230	1.65	5.67	7.16

In addition, variable flow simulation is defined  $Q_{var}$  for flows ranging from 0.10 to 1.10  $m^3/s$  in order to access low to medium flows below  $Q_{med}$ . Input flow hydrographs used as upstream boundary condition for H11 (Eastwood right branch) and  $H11_L$  (tributary left branch) and water levels used as downstream boundary condition for simulations  $Q_{var}$ ,  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  are shown in Figure 3.2-Figure 3.5 respectively.

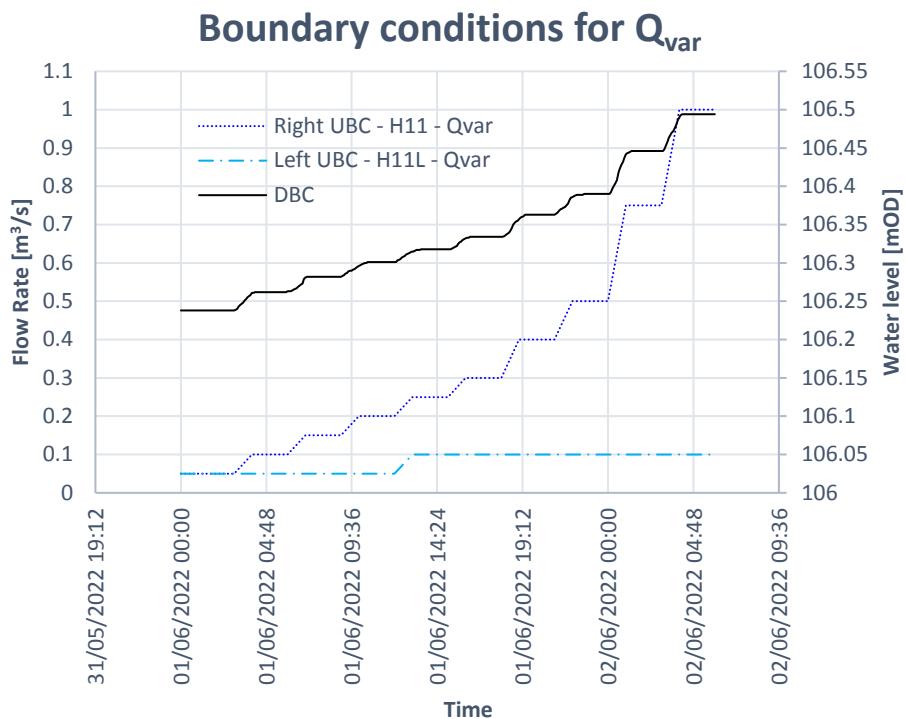

Figure 3.2. Boundary conditions for  $Q_{var}$  simulations (Existing and Design).

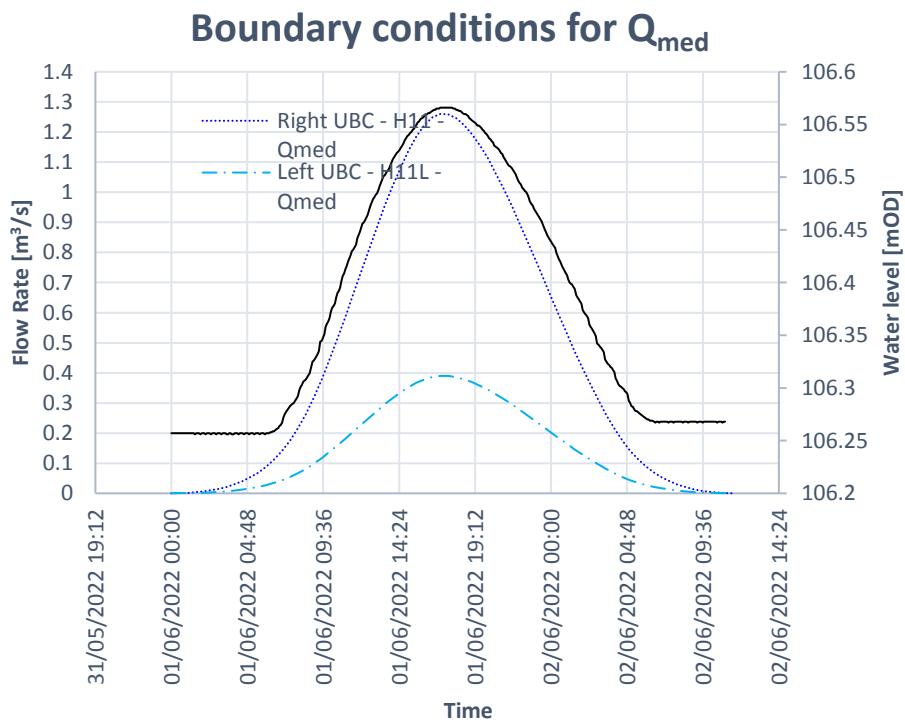

Figure 3.3. Boundary conditions for  $Q_{med}$  simulations (Existing and Design).

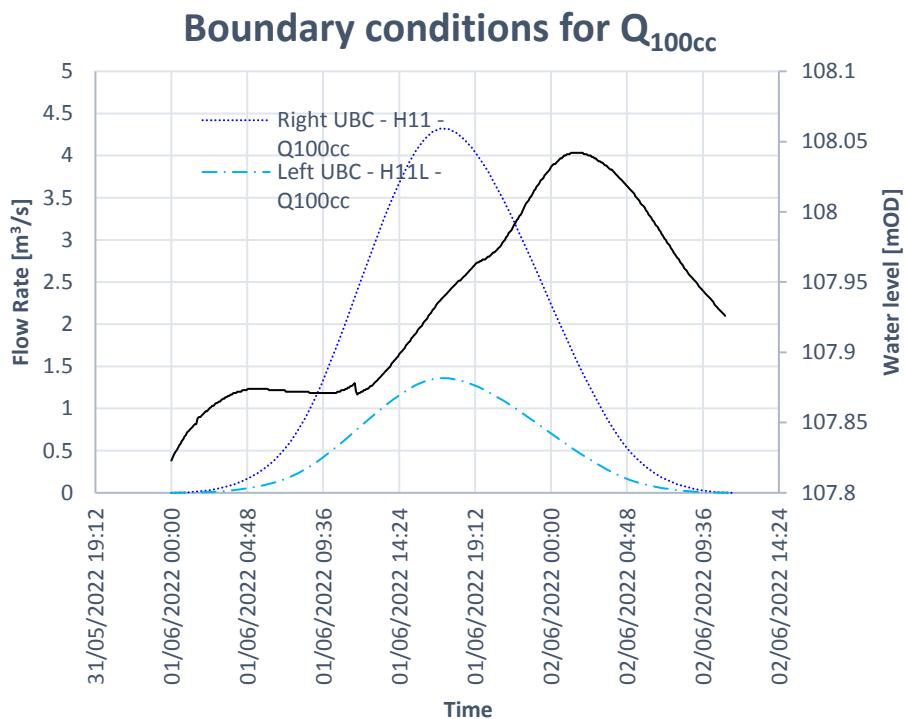

Figure 3.4. Boundary conditions for  $Q_{100cc}$  simulations (Existing and Design).

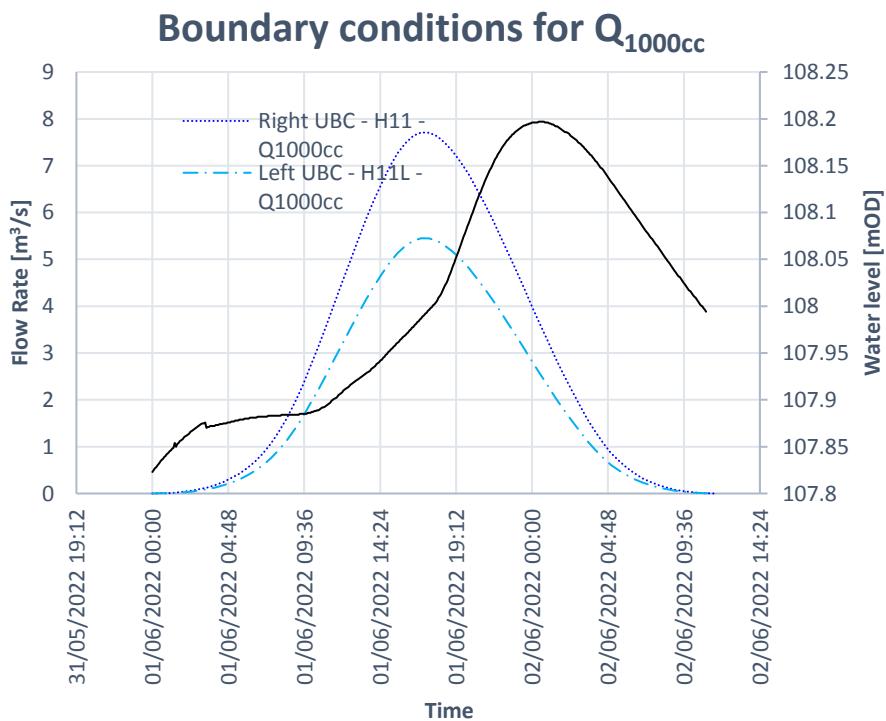

Figure 3.5. Boundary conditions for  $Q_{1000cc}$  simulations (Existing and Design).

## 4 Hydraulic simulations

### 4.1 METHODOLOGY

A full 2-D HEC-RAS computer model for varying flood flows is set-up to provide:

1. Hydrological/hydraulic simulations for the existing pre-development on the River Suir and flood plain site which give a benchmark for post re-meandering impacts.
2. Hydrological/hydraulic simulations to determine if there are any hydrological/hydraulic impacts adjacent to or downstream of the site.
3. Hydrological/Hydraulic simulations of the initial proposed stream and iterations leading to the final design.
4. Hydrological/hydraulic simulations of the final re-meandered reach to obtain all relevant data relating to the overall wind farm design and planning application.

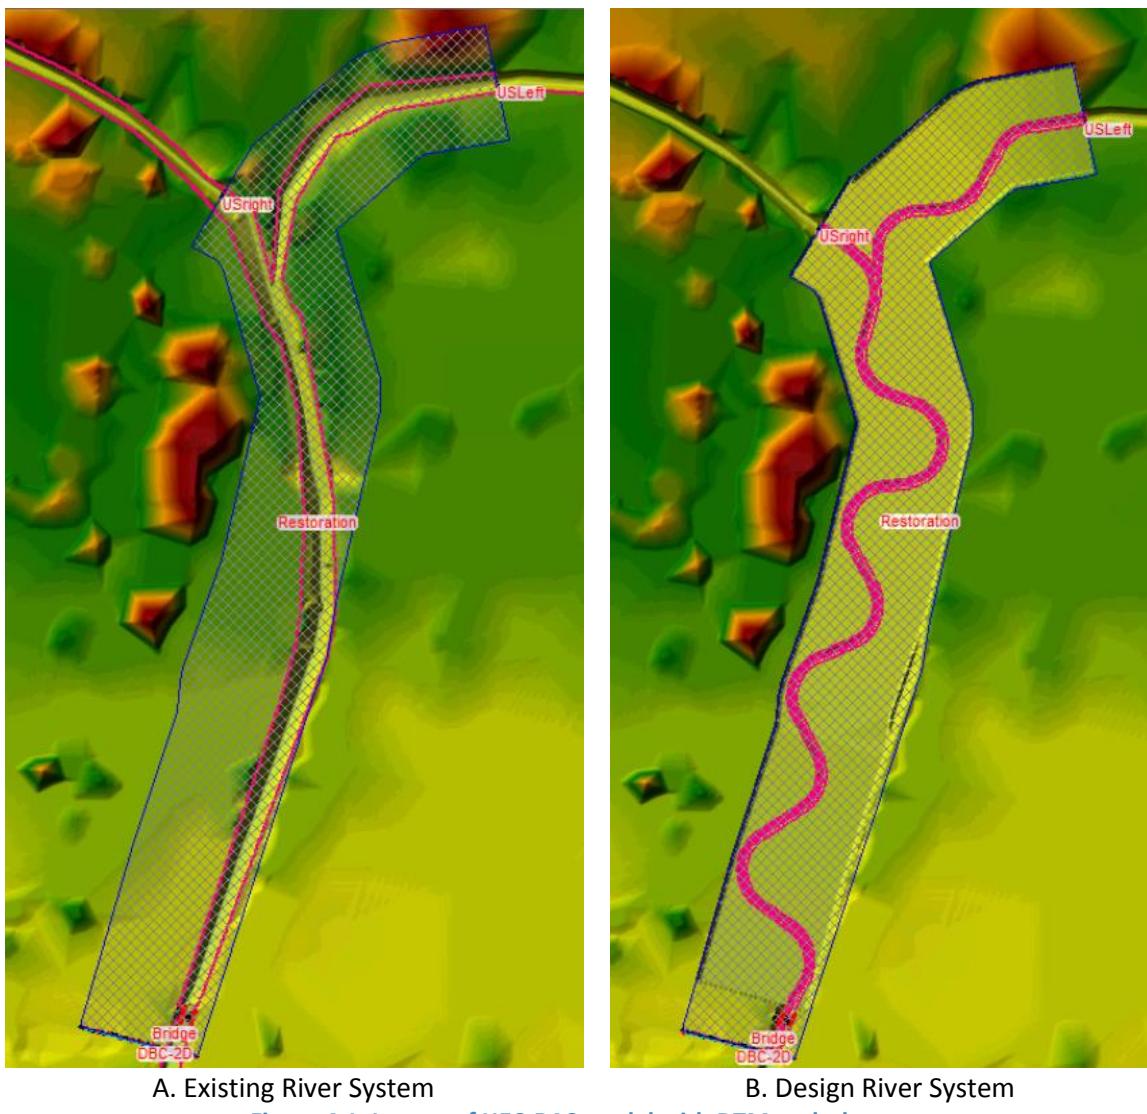

### 4.2 MODEL DESCRIPTION

A 300m long and c. 30m width full 2D Hec-Ras hydraulic model was developed for Existing and Design river system. The grid consists of maximum width of cell of 1m x 1m on the floodplain and 0.5m x 0.5m in the main channel (Figure 4.1). The Existing system includes the proposed windfarm road and culvert design and existing channels. The Design system includes re-alignment of the channel, involving re-meandering and construction of riffle-pool sections. In addition to this, estimates of the river channel and flood plain roughness (Manning's-n values) are estimated as they are required as input parameters and these were determined during a site inspection.

Models were developed for two River Systems:

- Existing River System which uses the geometry of the natural river channel and flood plains, including the final geometry of the proposed windfarm.
- Design River System that includes the final geometry of the re-meandered river reach and the geometry of the proposed windfarm.

The 2D model covers an area of 9000m<sup>2</sup>. At the downstream end of the model, the 1D Bridge structure (Bridge No. 17) was modelled and incorporated within 2D model domain. The layout of the HEC-RAS cross-section locations and DTM are shown in Figure 4.1.

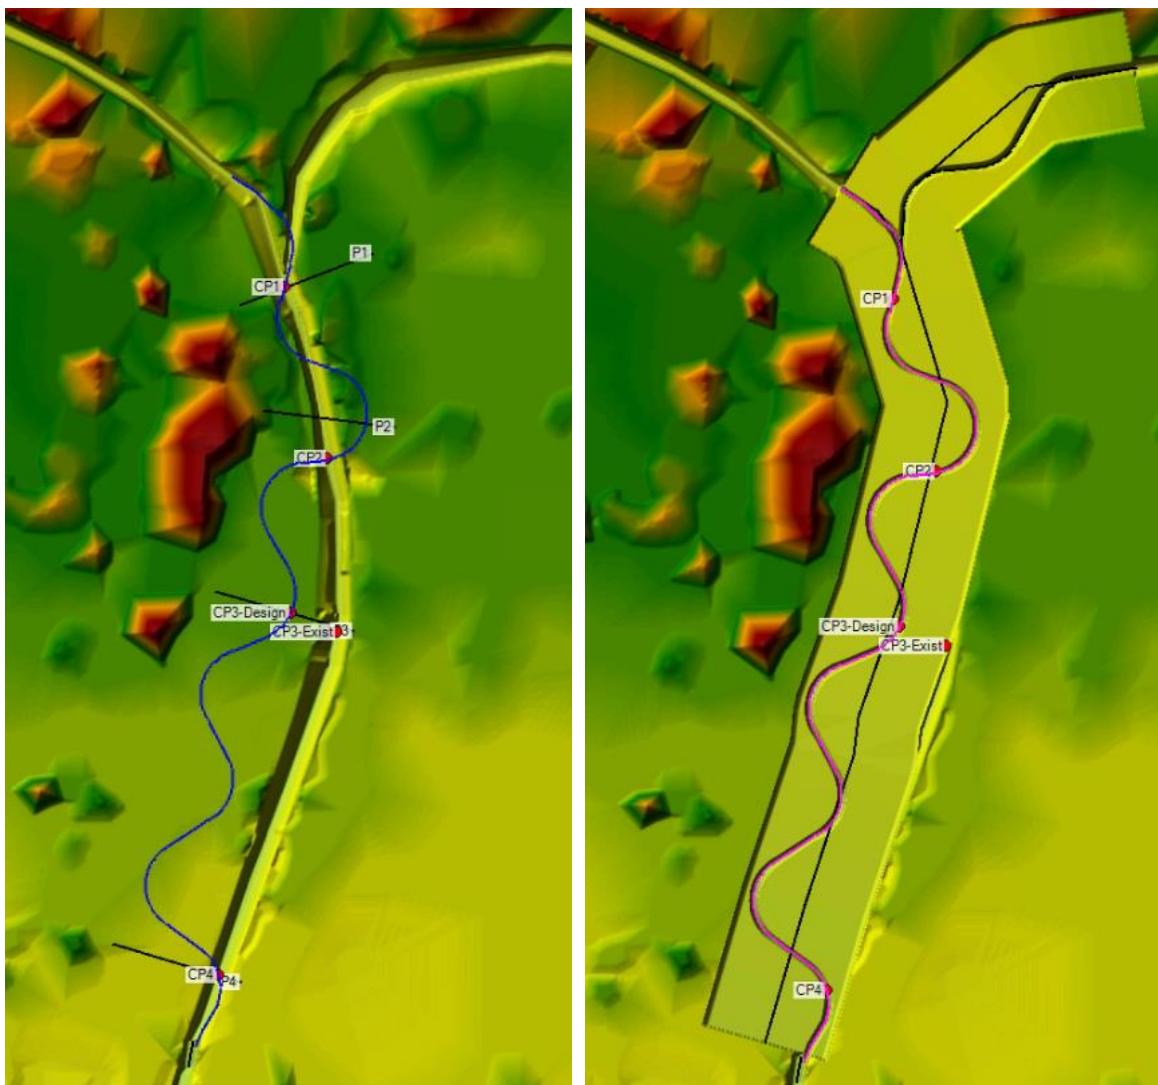

**Figure 4.1. Layout of HEC-RAS model with DTM underlayer.**

## 4.3 MODEL INPUT DATA

### 4.3.1 Geometry - Survey of river bed and flood plains

The first DTM describes the Existing River System<sup>1</sup> that includes wind turbine road network and new proposed culverts and flood plains (Figure 4.22A from FRA study [2]) and the second one describes the Design River System with an added meandering section with a 1m deep compound channel and nine riffles and pool sections (see (Figure 4.22B and Figure 1.3). Figure 4.22 also shows proposed enhancement work axis with control points and control cross sections.

**Figure 4.2. Comparison of Existing and Design Digital Terrain Models of the model area.**

<sup>1</sup> Design River System from FRA Study [2]

### 4.3.2 Upstream Boundary conditions

The upstream boundary conditions are defined as input flow hydrographs for simulations  $Q_{var}$ ,  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  are shown in Figure 3.2-Figure 3.5 respectively.

### 4.3.3 Downstream Boundary condition

The downstream boundary conditions are defined as water levels that were obtained in the following way:

- for  $Q_{var}$  and  $Q_{med}$  were obtained iteratively, e.g. calculated based on normal depth,  $d_n$ , with a defined energy slope of 0.008m/m and then obtained water level was used for both Existing and Design River system
- For  $Q_{100cc}$  and  $Q_{1000cc}$  were obtained from existing hydraulic model results [2] at the location of downstream boundary condition of the new hydraulic model

### 4.3.4 Roughness

Since previous model was 1D-2D model and the new model is a full 2D model, **roughness values for river channel and compound channel and floodplains have a Manning coefficient of  $n=0.030$ .**

## 4.4 SIMULATION EVENTS IN FLOOD RISK SCOPING

Using the HEC-RAS computer model, computer simulations were carried out for unsteady flow conditions using a flood flow value corresponding to the peak of the flood hydrograph. In summary the flood risk at the development site was analysed for four hydrological scenarios that cover the full range of flows from low flows to extreme flows, as shown in Table 4.1.

**Table 4.1. Design Events used in flood risk scoping**

Design event	Flow ID - Geometry	Downstream boundary condition – Water levels	Description
1	$Q_{var}$ -Existing	Varying WL	<b>Varying flows from 0.1-1.1 m<sup>3</sup>/s Existing</b>
1	$Q_{var}$ -Design	Varying WL	<b>Varying flows from 0.1-1.1 m<sup>3</sup>/s Design</b>
2	$Q_{med}$ -Existing	Varying WL	<b><math>Q_2</math> c. 2-year flood Existing System</b>
2	$Q_{med}$ -Design	Varying WL	<b><math>Q_2</math> c. 2-year flood Existing System</b>
3	$Q_{100cc}$ -Existing (20% climate change)	Varying WL	<b>Flood zone A - <math>Q_{100cc}</math>-Existing System</b>
3	$Q_{100cc}$ -Design (20% climate change)	Varying WL	<b>Flood zone A - <math>Q_{100cc}</math>-Design System</b>
4	$Q_{1000cc}$ -Existing (20% climate change)	Varying WL	<b>Flood zone B - <math>Q_{1000cc}</math>-Existing System</b>
4	$Q_{1000cc}$ -Design (20% climate change)	Varying WL	<b>Flood zone B - <math>Q_{1000cc}</math>-Design System</b>

## 4.5 COMPUTER MODEL RESULTS

The results are shown for Existing and Design River System for  $Q_{var}$ ,  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  year flow rates with included 20% increase of flows due to climate change (MRFS) as follows:

- Water levels at Control points CP1-CP4 (Figure 4.5-Figure 4.8)
- Flow rates at control cross sections P1-P4 (Figure 4.9-Figure 4.12)
- Water levels and terrain geometry at control cross sections P1-P4 (Figure 4.13-Figure 4.24)
- Longitudinal profile showing water levels at new meandering axis (Figure 4.25-Figure 4.26)
- Longitudinal profile showing flow velocities at new meandering axis (Figure 4.27)

The output locations, e.g. control points “CP’s”, Cross Sections “P” and longitudinal profile of a new meandering section are shown in Figure 4.3 and Figure 4.4.

Table output model results for  $Q_{med}$ ,  $Q_{100cc}$  (MRFS) and  $Q_{1000cc}$  (HEFS) is shown in Annex A. The Flow velocity distribution maps for  $Q_{med}$ ,  $Q_{100cc}$  (MRFS) and  $Q_{1000cc}$  (HEFS) are shown in Annex B.

#### 4.5.4 Longitudinal profile showing water levels at new meandering axis

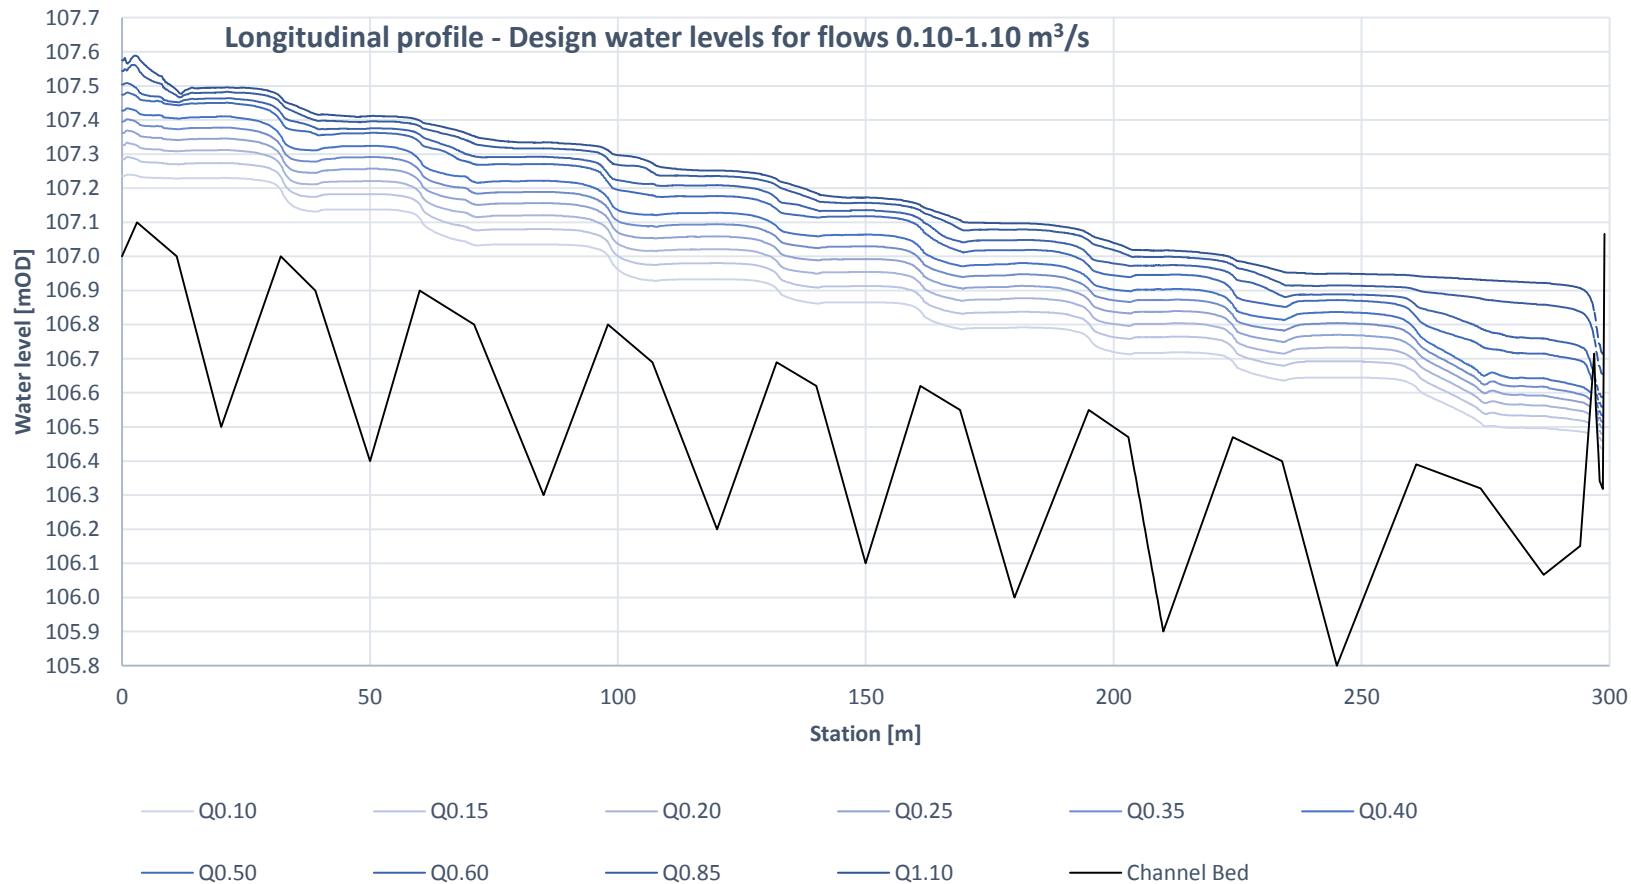

Figure 4.25. Longitudinal profile along the new re-meandered section showing Design water levels for flows ranging from 0.10 – 1.10 m<sup>3</sup>/s.

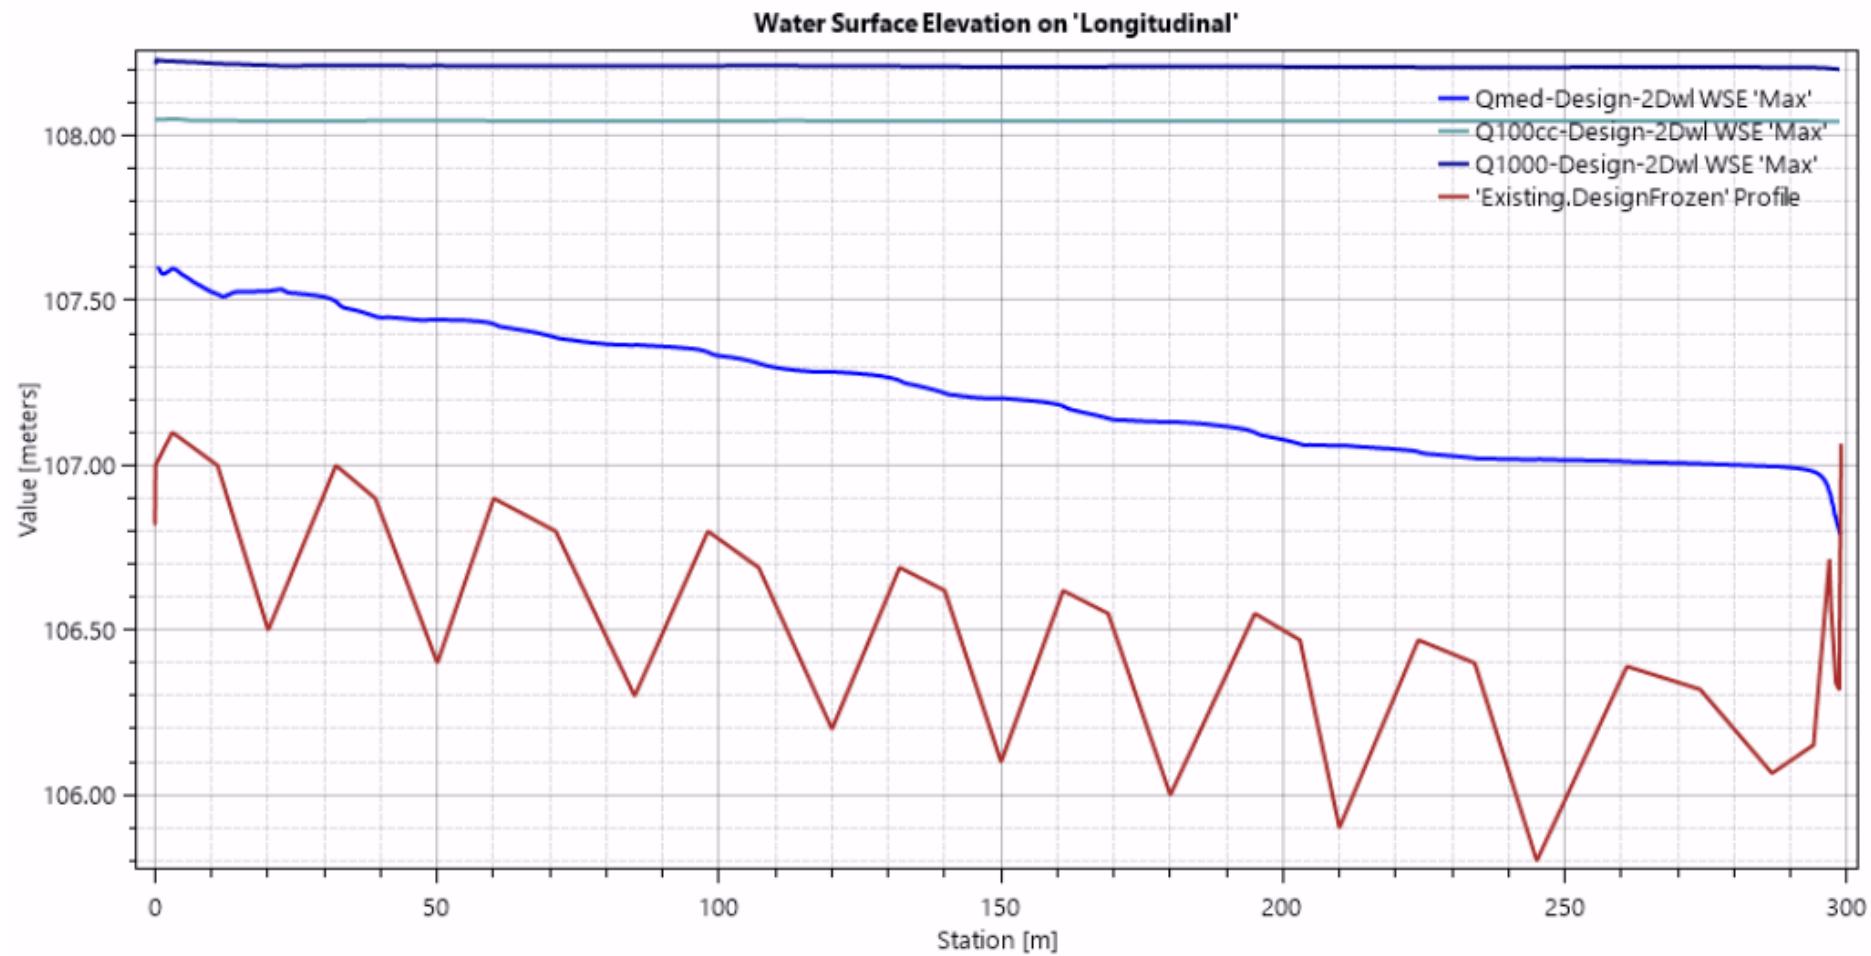

Figure 4.26. Longitudinal profile along the new re-meandered section showing maximum Design water levels for  $Q_{var}$ ,  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  flows.

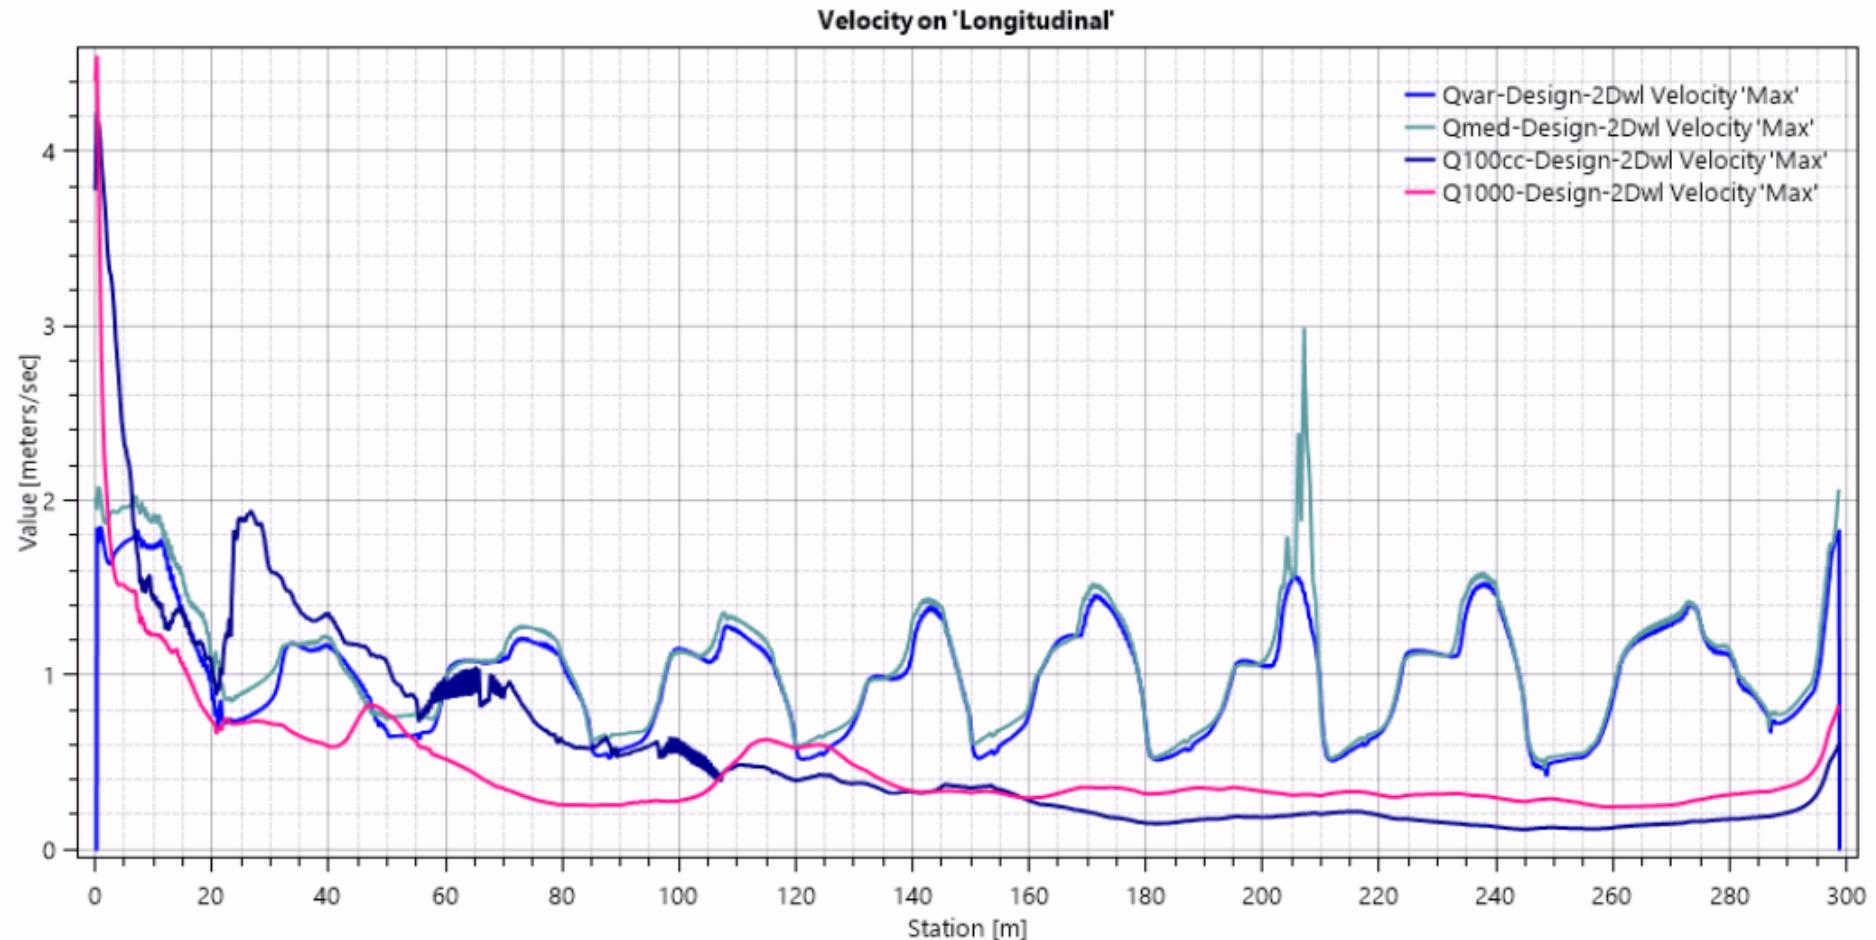

Figure 4.27. Longitudinal profile along the new re-meandered section showing maximum Design flow velocities for  $Q_{var}$ ,  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  flows.

## 5 Conclusions

1. Comparison of water levels shows that the Design River System gives lower water levels when compared to Existing River System for  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  flows (see  $Q_{med}$ ,  $Q_{100cc}$  and  $Q_{1000cc}$  results in Figures 4.5,4.6,4.7,4.8). This is due to additional storage provided by the newly formed compound channel incorporating the meandering main channel and the raised berm on either side that is on average 1m deeper than existing floodplain.
2. A slight increase of water levels for the Design River System is evident for very low flows below 0.40 m<sup>3</sup>/s (see  $Q_{var}$  results in Figures 4.5,4.6,4.7,4.8). This is due to the riffle sections and lower slope (0.0026 m/m) of the new proposed design channel when compared to the existing (straight) channel.
3. Comparisons of water levels were made at selected cross-sections and the results are given in Figures 4.13,4.14 and 4.15. These results confirm water levels reductions from Existing to Design scenarios.
4. The Design channel capacity is around 0.40 m<sup>3</sup>/s. This means that any flow greater than 0.4m<sup>3</sup>/s will spill out onto the compound channel berm but will have no effect on surrounding lands since the newly formed compound channel incorporating the meandering main channel and the raised berm on either side is on average 1m deeper than existing floodplain.
5. The model clearly showed that there is no increase of runoff i.e. flow rate, downstream of the re-meandered river reach (see Figures 4.9,4.10,4.11,4.12). Flow rate comparison showed that the difference between flow rates between Existing and Design River System is near zero for the full range of flows.
6. The flow velocities are noted to be the highest for  $Q_{med}$  simulations (near bank full flow flow) and are around 2.0m/s, with some localised areas up to 3.0 m/s. It is recommended that these areas are armoured to provide long term stability.

## 7.2 ANNEX B - FLOW VELOCITY MAPS

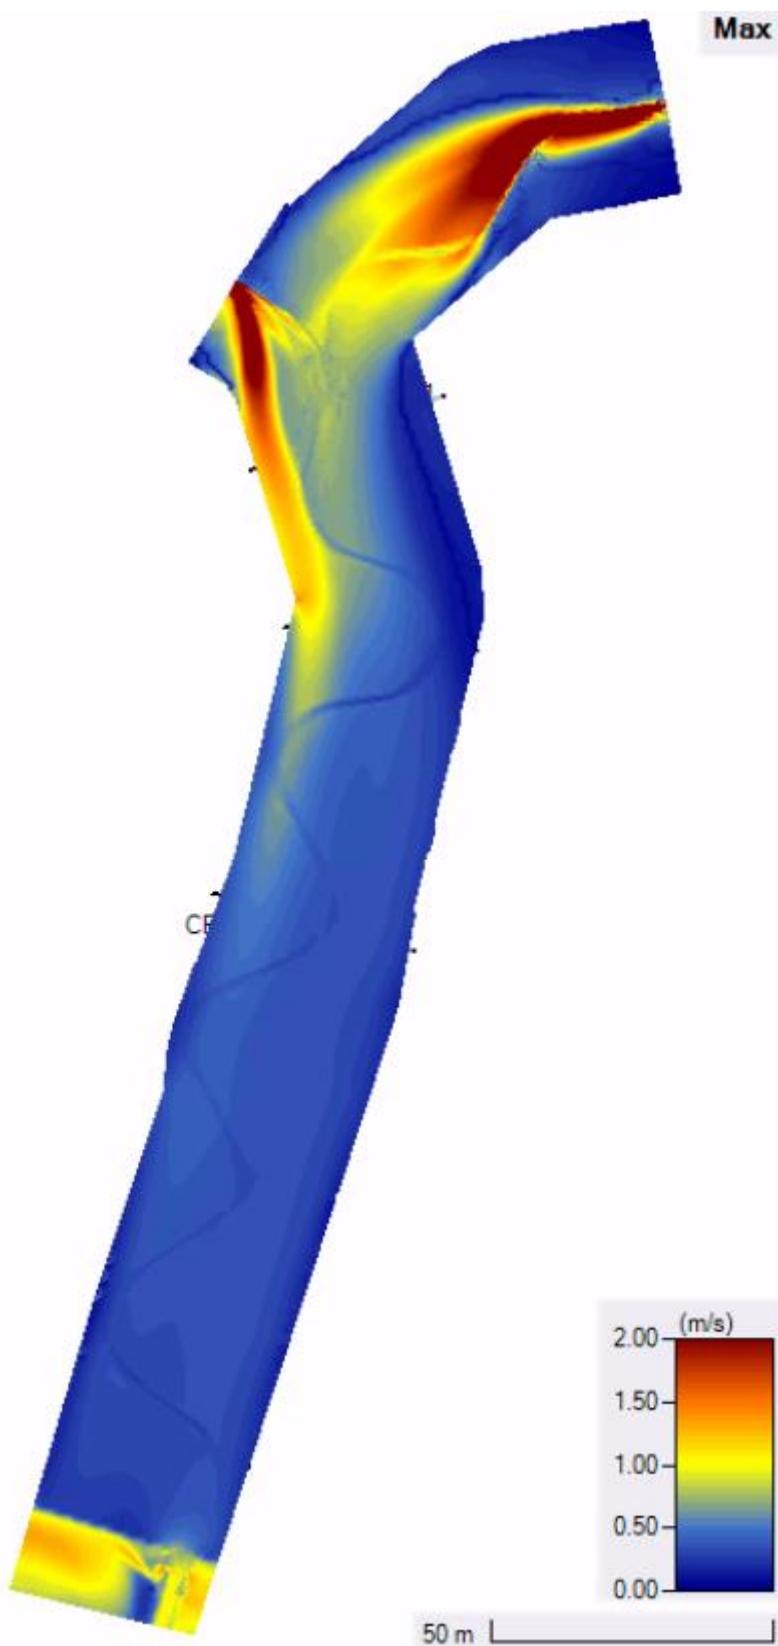

### 7.2.1 Velocity distribution for $Q_{med}$

## 7.2.2 Velocity distribution for $Q_{100cc}$

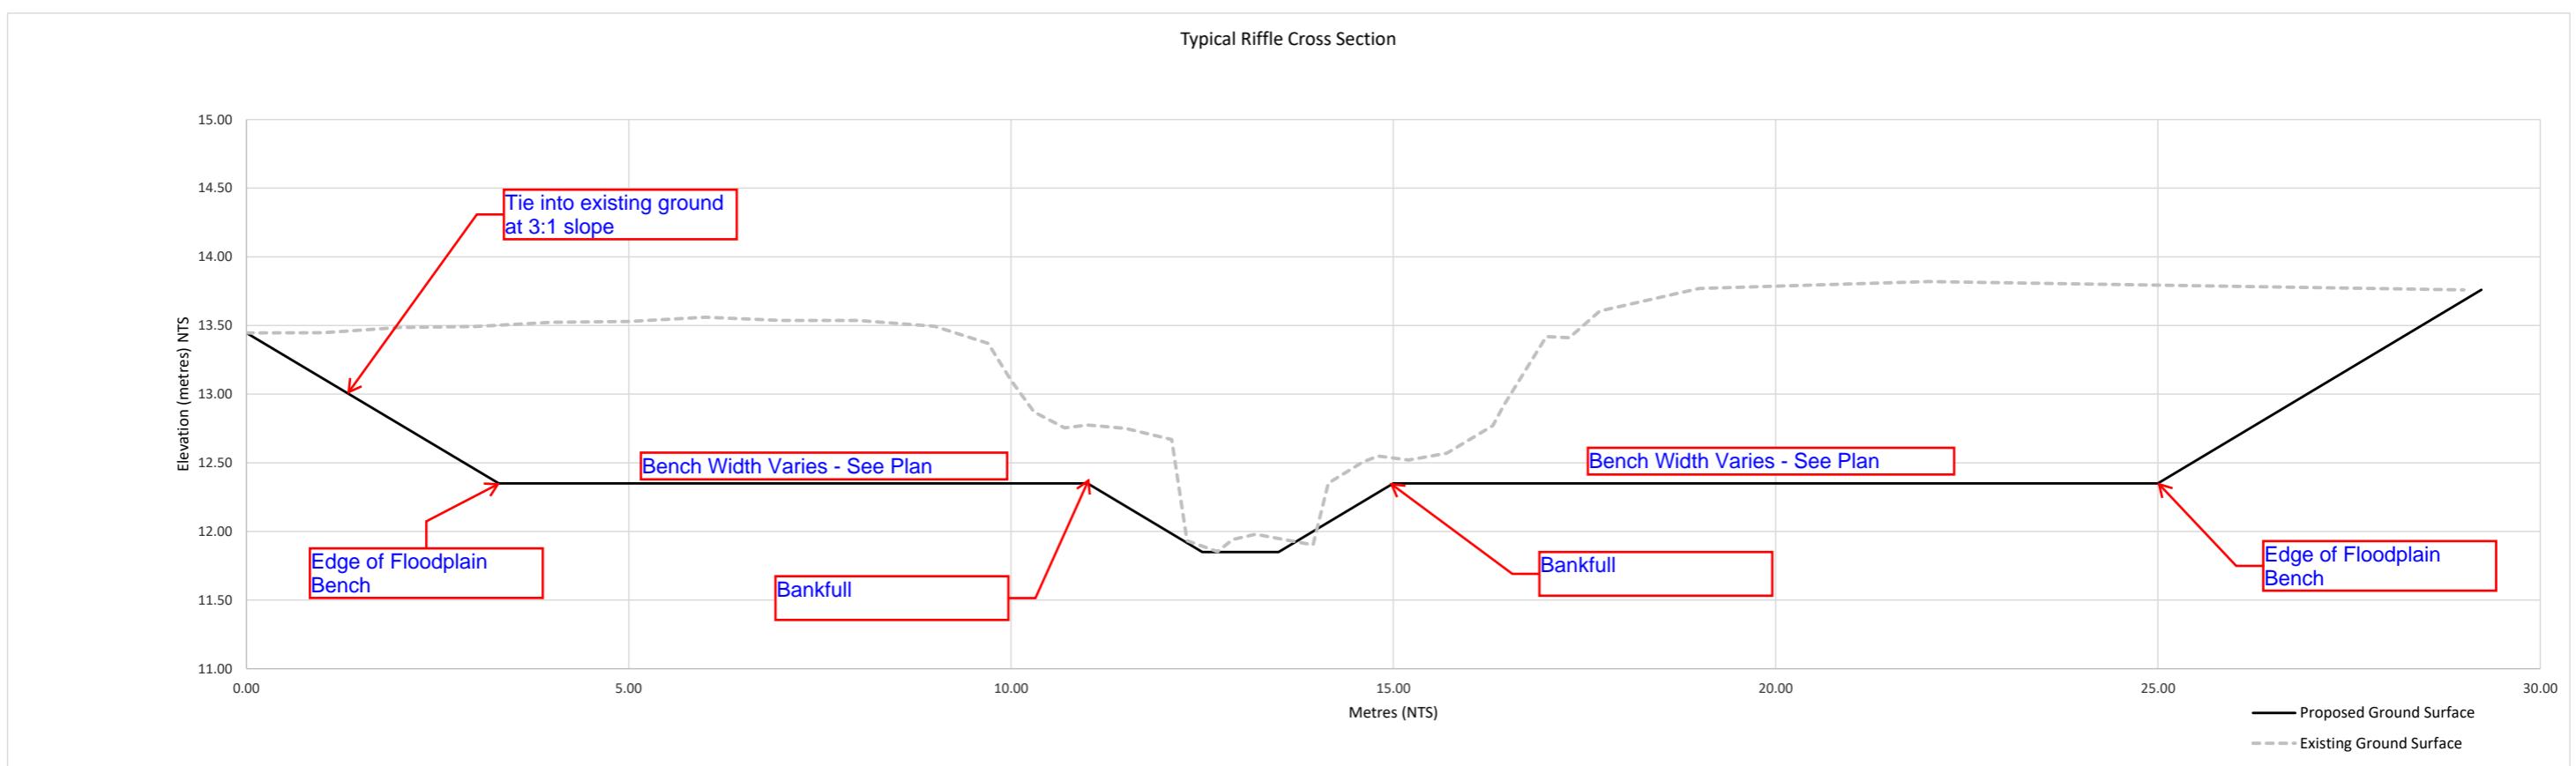

### 7.2.3 Velocity distribution for $Q_{1000cc}$

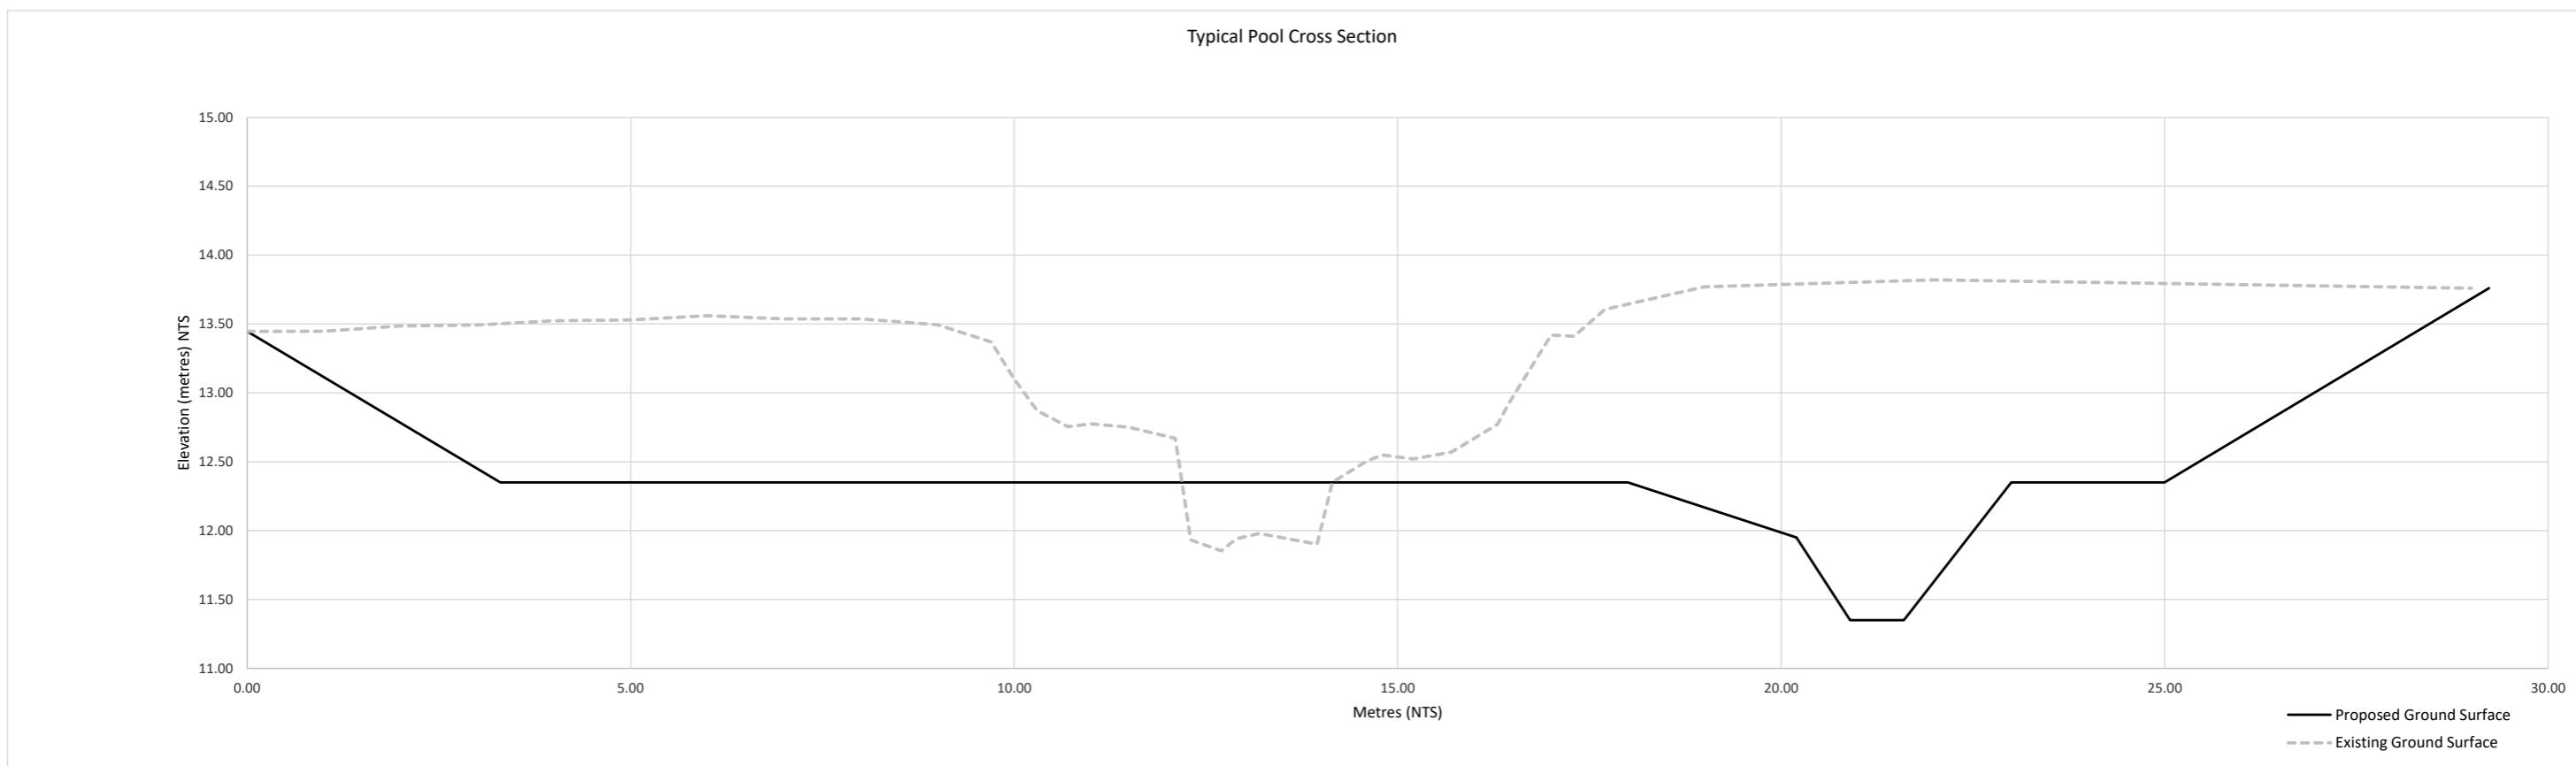

## 7.3 ANNEX C – TYPICAL RIFFLE AND POOL CROSS SECTIONS AND DESIGN LONGITUDINAL PROFILE

Typical Riffle Cross Section

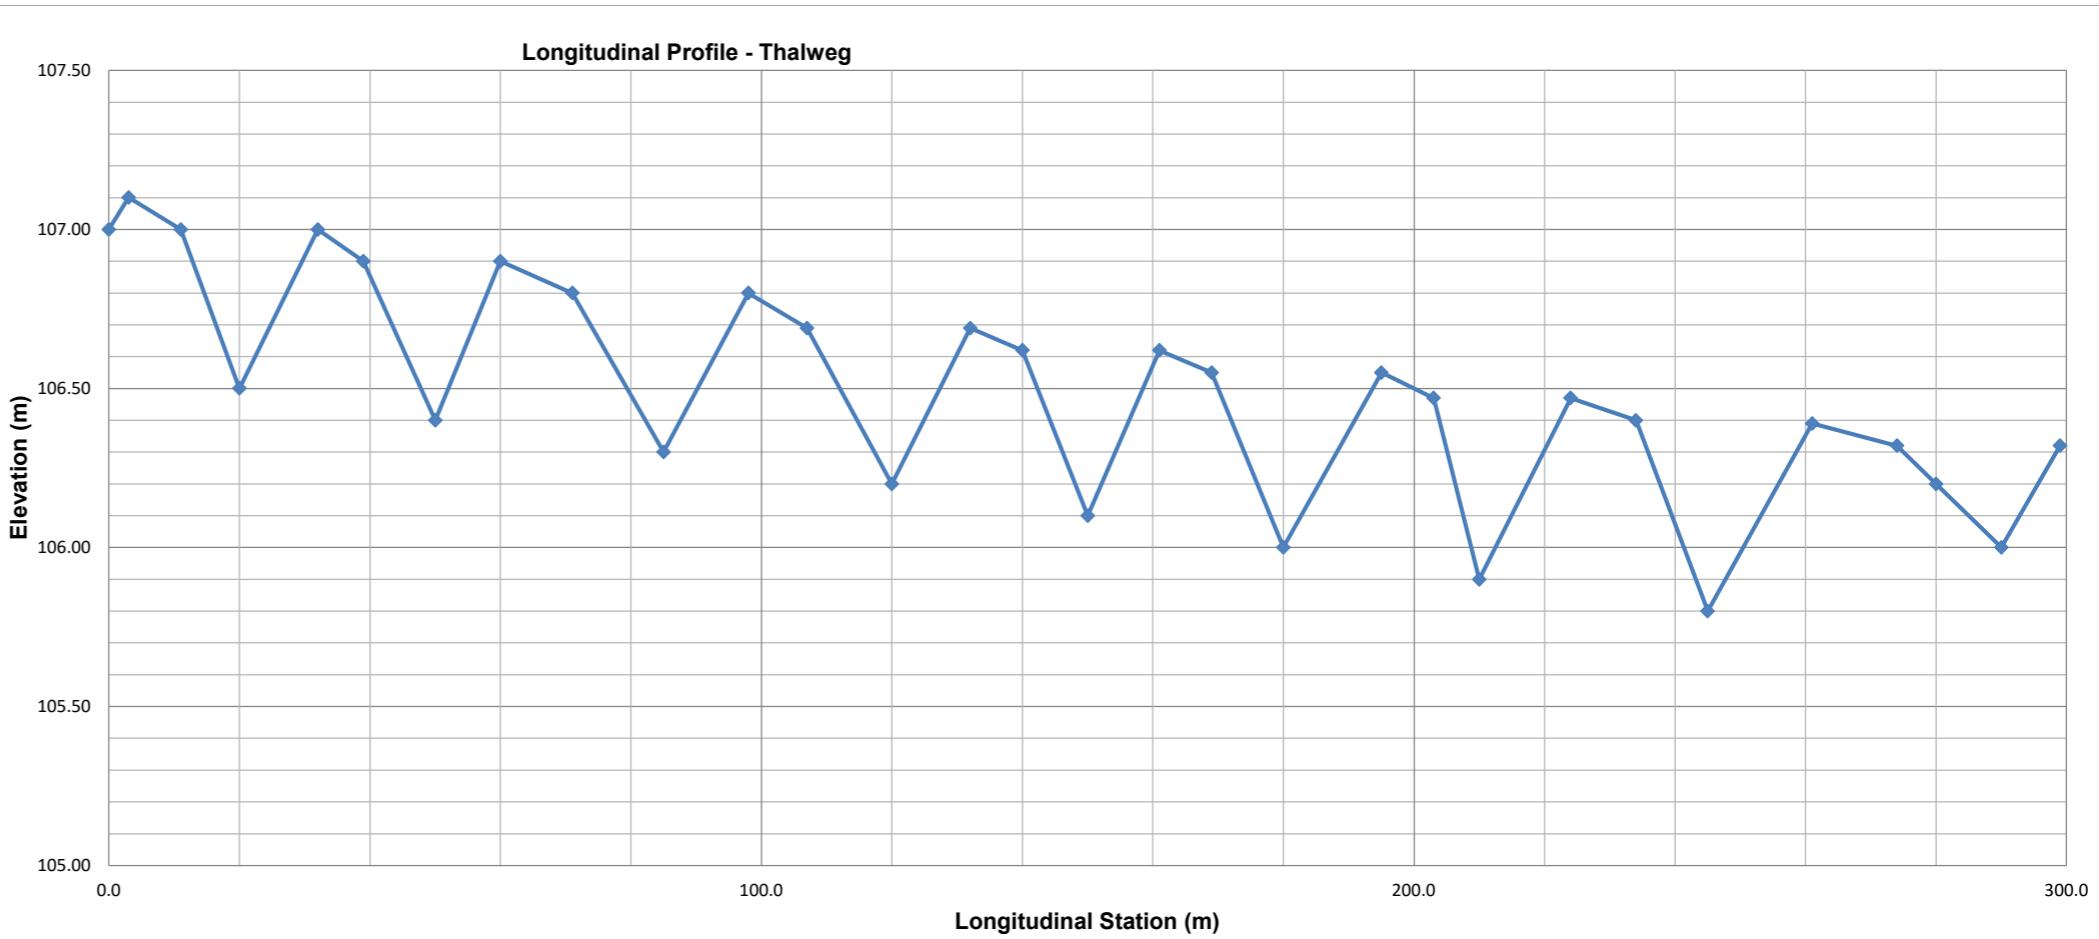

Typical Pool Cross Section

**Longitudinal Profile (Segment 2A)**  
*Enter data in shaded cells only*

	STA	ELEV
Begin	0.0	107.10
End	299.0	106.32

Val Length (m)	226.0
Chan Length (m)	299.0
Elev Change (m)	0.78
Chan Slope (m/m)	0.0026
Val Slope (m/m)	0.0035
Sinuosity, K	1.32
